CANADIAN ARCHITECT AND BUILDER.

VOL. XIII.—No. 11. NOVEMBER, 1900 { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER.

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited, Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to foreign subscribers is $2.50. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1900.

PRESIDENT -	A. FRANK WICKSON, Toronto.
1ST VICE-PRESIDENT	FREDERICK HENRY, London.
2ND VICE-PRESIDENT	GRANT HELLIWELL, Toronto.
TREASURER -	F. S. BAKER, A.R.I.B.A., Toronto.
REGISTRAR -	W. R. GREGG, 61 Victoria St., Toronto.

COUNCIL:

J. E. BELCHER, - - - -	Peterborough.
S. H. TOWNSEND - - - -	Toronto.
W. A. LANGTON - - - -	Toronto.
J. A. PEARSON - - - -	Toronto.
A. H. GREGG - - - -	Toronto.

Communications are addressed to the Registrar.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1899.

PRESIDENT - -	G. E. TANGUAY, Quebec.
1ST VICE-PRESIDENT -	J. VENNE, Montreal.
2ND VICE-PRESIDENT -	W. E. DORAN, Montreal.
SECRETARY - -	G. A. MONETTE, Montreal.
TREASURER - -	J. S. ARCHIBALD, Montreal.

COUNCIL:

PROF. S. H. CAPPER - - - - - -	Montreal.

Inspection of Elevators.

A COMMITTEE of the City Council of Toronto has under consideration the subject of the inspection of elevators by the municipality. Considering the number of accidents which have occurred, there appears to be need for such inspection. The number of elevators in use in the city is placed at 1,000 and the number of persons using them at 40,000. Presuming this estimate to be approximately correct, it will be seen how great is the liability of accident if the mechanism of these elevators, and the competency of the persons who may be placed in charge of their operation, is not placed under proper supervision and control.

Soldiers' Memorials.

Fitting public recognition has been made of the services rendered to Canada and the Empire by the members of the first Canadian contingent who recently returned from South Africa. Without doubt a hearty welcome home also awaits the members of the second contingent on their return. But what of the brave lads who laid down their lives in defence of the flag? It is not too early to consider what steps should be taken to express in the form of permanent and suitable memorials the nation's undying appreciation of their valor. While public enthusiasm is aroused as never before in our history, this matter should receive attention. In addition to a National memorial at Ottawa, there should also be memorials erected in the principal cities of the various provinces of the Dominion. Toronto probably could not do better than erect a permanent memorial arch on the site of the temporary one at the entrance to Queens Avenue through which the soldiers passed on their return to the

city. Such a memorial would form a fitting contrast in character to those already placed in Queen's Park to commemorate the death of the volunteers who fell in action at Ridgeway and in the Northwest Rebellion. It would also add interest and dignity to the approach to the Park and Legislative Buildings. The designs for the memorials should be obtained by competition, limited or otherwise, as might be considered conducive to the best result.

German Cement Combine.

FOLLOWING the example of their British confreres, the German manufacturers of Portland cement propose to organize a combine to restrict the output to the average quantity sold during the past three years with a fixed allowance for improvements and for new factories. The present output of the German factories is about six and a half million tons, while the consumption amounts to only four millions. New factories are also being built, with a capacity of two and a half millions. The British, Canadian and American manufacturers are thus likely to be saved from the price-cutting competition which must have resulted from the efforts of the German manufacturers to dispose of their large surplus production in the foreign markets.

Students' Competitions.

ATTENTION is called to students' competitions, particulars of which are printed in this number. The busy season is about to close. The long winter evenings are almost here. The students' opportunity for study and self-improvement is at hand. The student who is alive to his future interests will make profitable use of his time and opportunities this season. It is by placing one's effort's alongside those of others, that one is able to judge of his knowledge, abilities and progress. Every architect should feel an interest in his students. One way of manifesting that interest would be to call their attention to these competitions and encourage them to enter. Will every Canadian architect who may read these lines lend his co-operation in this direction? If so the success of the competitions will be assured.

The Teaching of Drawing.

AMONG the international congresses held in Paris during the last summer was one on "The Teaching of Drawing," which opened on August 29th and closed on September 1st. As the result of a full discussion of the subject, first in separate sections and afterwards in full assembly, the following conclusions were reached. (1.) That drawing should be made a compulsory subject in general education. (2.) That the initiative of the teacher and the individuality of the student should be encouraged to the fullest degree possible. (3.) That the artist and workman should be brought into closer contact by the former devoting greater attention to the requirements of the trade for which he designs and by providing for the latter a more liberal art education. (4.) That the architect requires a more scientific training and the engineer a more artistic training in order that the two professions may work in closer contact with each other.

Opportunities for Trade Expansion.

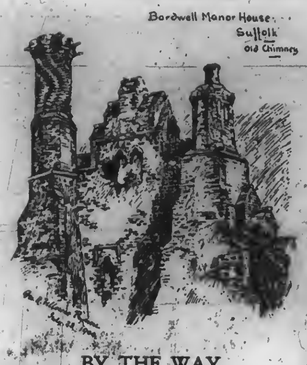
THE return of the Canadian contingent from South Africa reminds us that the war is now drawing to a close and although it may be some time before it is entirely over, trade there is just beginning to resume its former shape. There is little doubt that as soon as security to those commercially engaged can be depended upon, a very considerable expansion in trade may be expected. Tariff rates in the two states which have recently been annexed to the British Empire were formerly almost prohibitive, so that when this new field can be added commercially to that already known in Cape Colony and Natal, the market should be one worth enquiring into. Another change in the Empire is to be made on January 1st., when the Australian colonies are to be federated into one Commonwealth which will necessitate a revision of tariff rates as each colony had its own tariff. It would therefore probably be a suitable time for persons interested in the expansion of trade to enquire into the chances to be found in this field for Canadian products.

Shingles.

IT has been interesting to watch the struggle for popular favor between the different varieties of shingles. Our observations lead to the conclusion that the white pine shingle is losing ground, and that its field is gradually becoming more limited. In the western part of Canada, for instance, preference is given to the red cedar shingles, while in eastern Canada the white cedar shingle is largely used. In Ontario the white pine shingle may be said to still hold the market, but even in this province it is meeting with severe competition from other varieties. One of the reasons for this encroachment on the white pine field is the comparatively lower price of cedar shingles. Another reason which has been advanced is that the quality of the white pine shingle is deteriorating, and that even the clear butts sometimes have worm holes in them. It is unlikely that the manufacturers of white pine shingles will endeavor to materially improve the quality of their production, as the high price of pine stumpage makes it necessary to convert into shingles only that portion of the logs which will not make merchantable lumber. It is a significant fact also that the red cedar shingle as now manufactured is a much better article than that which was submitted to the eastern trade a few years ago.

Storage of Explosives.

THE disastrous explosion which recently occurred in a wholesale drug warehouse in New York, has called attention to a source of danger which appears to have been to a large extent overlooked. True, the building regulations of most of our cities contain a regulation prohibiting the storage of any considerable quantity of explosives within specified districts. Such a regulation appears to have existed in New York, but its enforcement was not properly looked after, and the present disaster to life and property is the result. This occurrence should lead to an investigation by the municipal authorities of Canadian cities, to learn if the provisions of the building by-laws in this particular are being observed. The liability of insurance companies for damage arising from explosions of this character also enters into the question. We observe that the standard insurance policy in New York provides that the insurance companies shall not be liable for loss caused by explosions of any kind, unless fire ensues, and in that event for the damage by fire only. The plate glass insurance companies have refused to assume liability for damage to windows within the area damaged by the explosion. It will thus be seen how important are the interests hinging upon the proper enforcement of regulations for the prevention of storage of explosives within the central districts of towns and cities.



BY THE WAY.

THE Assessment Department of Toronto estimates that there are now in that city only 630 vacant houses, and 131 vacant stores, as compared with 3,311 vacant dwellings, and 648 vacant stores in 1896, and that to meet the requirements of population 1,200 houses must be built next year.

\+ + +

THE multiplicity of strikes and their far reaching effects upon the welfare of the persons immediately concerned as well as upon the industrial progress of the Dominion, necessitates the adoption of legislation which would be effective in putting a stop to this method of settling disputes between capital and labor and such scenes as were recently witnessed at Valleyfield. Compulsory arbitration on similar lines to the New Zealand law seems to be the best solution of the question.

\+ + +

I AM pleased to note that the teaching quality at the Toronto Technical School is being improved. Mr. Barrett, a capable young architect, was recently appointed instructor in Building Construction. Mr. Banks, whose skill as a modeller is well known in Toronto, has been engaged to give instruction in modelling. If the services of equally well qualified teachers can be procured for the other departments the school may be expected to do much better work in the future than in the past.

\+ + ×

THE authorities of Queen's University, Kingston, have issued an invitation to architects to submit plans and designs for new buildings to cost about $150,000. It contains the usual clause that the said authorities do not bind themselves to accept any of the plans submitted. No provision is made for the appointment of an expert to judge the plans. The matter has been brought to the attention of the Ontario Association of Architects who will try to enlighten the authorities regarding the conditions which should govern competitions of this kind. No self-respecting architect should have anything to do with the competition in its present form.

\+ + +

THIRTY TWO granite columns each 54 feet long, by 6 feet in diameter, and weighing about 160 tons, are to form a feature of the construction of the cathedral of St. John the Divine, New York city. The rough blocks of granite from which these columns are made, each measure 67 feet long, 8½ and 7 feet cross section, and weigh 310 tons. The corners are roughly dressed off by hand, after which the block is placed in a lathe 86 feet in length, having a swing of 6 feet 6 inches by 60 long, fitted with eight cutting tools, each of which takes a cut 3 inches in depth. These cutters reduce the diameter of the block by 24 inches at one passage over its surface. Six weeks are required to dress and polish each column.

\+ + +

THE Builders' Journal refers to the foolish custom still prevailing at Freiburg, in Germany, of offering a reward of five shillings and a good dinner to the steeple jack who will climb to the top of the tower of the Minster, a height of 400 feet. This performance forms a feature of the celebration of the birthday of the reigning Grand Duke of Baden. In the ascent the men have to leap from stone to stone, and as the space between these is considerable in some cases, it will be seen what an idiotic practice this is; one miss and the man would be dashed to the ground. When the top is reached a pistol is fired and then the descent is made. Three men went up the tower the other day, and one of them performed acrobatic feats on an iron bar fixed about half-way up.

\+ + +

THOSE who have studied the methods of the trades unions have noticed that the chief object sought to be attained by them is to secure for their members the highest possible renumeration for the least amount of skill and labor. The working hours have been reduced from ten to nine; again in many cases from nine to eight. This rate of progress is too slow however, for some of the more advanced thinkers on this subject, in which class deserves to rank the Rev. S. S. Craig, a representative of what is called the People's Party. This gentleman in an election address delivered in Toronto, is reported to have said: "He was glad to see the eight hour working plank. But he wanted something more; he wanted a four hour working day and the taxation of land values would produce a four hour working day. Then our wives and our daughters would not have to leave their homes to work for a living, and everbody would have full opportunity for work." Isn't it the opportunity to escape work that is being sought for?

\+ + +

A GENTLEMAN who has recently visited Sydney, C. B., has been telling me of the wonderful development which has taken place in that town since it became known that the Dominion Steel Company had decided to establish extensive works there. Property which before was considered to be of little value, has enormously advanced in price; indeed it is stated that owners do not apparently know how much to demand, and the prices asked are in many instances ridiculously high. The Bank of Montreal is said to have paid $8,000 for a site sufficient for a new building on one of the principal corners. The number of stores and high class stocks therein is said to be entirely out of proportion to the requirements, as the majority of the new population which has been brought into the town, in consequence of the operation of the steel company, principally consists of the laboring class, whose wages are small and who therefore can purchase only the cheaper class of goods. After a time, when the works are constructed and put in operation, a larger proportion of skilled workmen will be employed at higher wages, but even then it is considered doubtful if many of the new establishments which have been started will find it possible to do a profitable trade.

The Keizer Brick Machine & Mfg. Company, of Winnipeg, are applying for incorporation.

ARCH OF TRIUMPH, PARIS.

CANADIAN SOLDIERS' MEMORIALS.

By request a number of gentlemen prominent in artistic, military and business circles have kindly sent us a brief expression of their views in regard to the desirability of immediate action being taken to erect suitable memorials to the memory of the Canadian soldiers who fell in defence of the Empire in South Africa. These opinions are appended as follows:

GENTLEMEN,—I have your valued favor of Nov. 8th and have read the accompanying proof of the proposed article in relation to a Memorial of the participation of Toronto in the South African War, and in reply have to say that I think it is desirable that while the public is alive to the question, some means of recognition should be adopted. Your article doubtless will provoke discussion, and enable those interested to form a better opinion than could be done off hand without greater consideration than I have been able to give to the question.

It has occurred to me that the men who sacrificed their lives in this War, should especially have recognition, and whether the Arch is erected or not, the portraits of these men who went from Ontario, should be placed in the Parliament Buildings.

I know that in some cities of the United States, the representatives who perished in the War of the Rebellion, have been honored in the way which I have indicated—thus, in Harvard College there is a Memorial Hall devoted entirely to this purpose.

Yours very truly,
EDWARD GURNEY.

SIR,—Replying to yours of yesterday's date, I quite approve of the "Soldiers' Memorial" exactly on the lines that you suggest. I think it is the duty of the citizens of Toronto to in some satisfactory manner permanently commemorate the men who went to South Africa, and I think no better form could this memorial take than a permanent archway where the temporary one was erected at the end of Queen Street Avenue. Appreciating the honor you do me in asking my opinion, believe me,

Yours truly,
JOHN I. DAVIDSON.

Toronto Nov. 10, 1900.

DEAR SIR,—I was very pleased to receive a few minutes ago, your circular letter respecting a permanent arch to be erected in Toronto as a fitting recognition of the services that Canada's sons have rendered to the Empire. I would suggest; however, that a better and safer location than the one you mention would be at the College street end of the avenue. Queen street being such a thoroughfare, I fear the same difficulty in preserving it would occur as what happened to the fence around Osgoode Hall, where every corner of the stone pilars was broken off by hoodlums loitering around in that vicinity. I think the arch should be of substantial stonework, and as it would be at the very entrance of Queen's Park, that a statue of Her Most Gracious Majesty, the Queen, should adorn the top of the arch. I am quite sure if the ladies of Toronto would take this matter up, they would carry it through to a successful issue, as they have never yet failed in any undertaking of a loyal and patriotic nature. Wishing you every success and assuring you of any assistance I can possibly afford,

Yours faithfully,
J. M. DELAMERE,
Lieut.-Col. Com. Q.O.R. of Canada.

GENTLEMEN,—Replying to your letter of the 8th inst., enclosing copy of article referring to a suitable memorial for our Canadian boys who have died for the Flag in Africa, I would say that I am in sympathy with the idea, and think that some recognition should be made in the shape of a memorial in the Queen's Park. They certainly have done their duty well and faithfully, and we are under a deep debt of gratitude to them.

Yours faithfully,
A. E. KEMP.

DEAR SIR,—I am heartily in accord with the proposition to erect a memorial to those Canadians who gave their lives for the cause of freedom in South Africa, and as a Canadian artist I am jealous that the memorial shall be a fitting tribute in its aspect as a work of art. I approve of obtaining designs through competition, but only on condition that a competent jury is appointed to decide on the merits of the designs. The Toronto Guild of Civic Art is organized for the purpose of arranging such matters, both as to how designs should be submitted and the appointment of fit persons to pass judgment upon them, and I hope the arrangement of the purely artistic portion of the work will be entrusted to that body. I would suggest, as a practical step to take, that the Guild be asked to look into the matter, and prepare several alternative schemes with the approximate cost of each. Speaking as a member of the Guild, I believe immediate action on their part would result from such an invitation from the Red Cross Society, who have initiated the idea.

Sincerely yours,
G. A. REID.

INDIAN ROAD, TORONTO, NOV. 13TH, 1900.

DEAR SIR,—I wish to assure you of my sympathy with your proposal to erect a memorial to members of the Canadian Contingent who fell in South Africa. Some memorial should be erected and it is time now to make suggestions. But as regards the especial memorial you propose—an arch over Queen's avenue—I hesitate to express unqualified agreement. If it were intended to raise a memorial to troops returned from victory, such an arch as they might march under on the day of their return would be a suitable memorial; the present custom for temporary decorations and precedent for permanent structures suggests it. But as an erection in honor of the dead, it seems, whether innately or from custom, inappropriate.

I offer this criticism of the particular proposal made, but hope, and indeed cannot doubt, that the general idea will meet with approval from everybody.

Yours truly,
W. A. LANGTON.

94 KING ST. WEST, TORONTO, Nov. 12th, 1900.

DEAR SIR,—I think the proposal to erect a permanent memorial to our Canadian Soldiers on the site of the temporary triumphal arch is a very good one.

But I hope if this work is undertaken at all it will be done as well as they did their's.

An important opportunity like this of permanently recording a great event in our country's history should be thought out as well as we are able, so that there will be no risk of belittling either the deeds of our soldiers, or a site so valuable with a mean erection.

The Guild of Civic Art was formed I believe to advise upon these matters and I hope they will see that the project is dealt with in a large enough manner, and not leave us with a monument like something adrift from a graveyard.

Yours truly,
EDEN SMITH.

CANADA LIFE BUILDING TORONTO, Nov. 13th.

DEAR SIR,—I have read your suggestion that an arch should be erected at the foot of Queen's Avenue to commemorate the bravery of the Canadian troops in South Africa. I heartily approve of the suggestion. The co-operation of the colonies with the mother land marks clearly an epoch in our history, and no more appropriate form of monument could be erected than an arch. The position is an admirable one, and I think the Ontario government should unite with the city in erecting an arch that would reflect credit on our country and city.

Yours truly,
JAMES L. HUGHES.

TORONTO, Nov. 13th, 1900.

GENTLEMEN,—I duly received your favor enclosing a circular with reference to the proposed memorial to those of our volunteers who were killed and wounded in South Africa.

I agree with your idea that a permanent memorial arch should be erected on the site of the temporary one at the entrance to Queen's avenue, and shall be pleased to subscribe to a fund for that purpose, providing the matter is dealt with promptly.

Yours truly,
J. O. THORN,
Honorary Captain, Quarter-Master, 2nd Regiment Queens' Own Rifles of Canada.

TORONTO, ONT. Nov. 14, 1900.

DEAR SIR,—Our society having heard from Mr. Reid, our President, of the intention to erect an arch to commemorate the death of our soldiers who fell in South Africa, heartily endorse the suggestion, and would advise that all our architects and artists be invited to send designs, and that judges appointed by the Guild of Civic Art select the most artistic and suitable for the purpose.

Yours truly,
ROBT. F. GAGEN,
Secretary Ontario Society of Artists.

TORONTO, Nov. 14, 1900.

DEAR SIR,—Relative to your suggestion regarding a memorial to be erected in honor of the brave Sons of Canada who have laid down their lives in defence of the Empire in South Africa, I think there cannot possibly be two opinions upon the advisability of erecting some permanent and suitable monument in recognition of their services.

What is done, however, should be done well. The monuments now existing in Queen's Park commemorating the death of those who fell at Ridgeway and in the North West Rebellion, are not, in my opinion, worthy of the deeds which they commemorate. Any monument which may be erected to the memory of those who fell in South Africa should be one in which we can always take a pride in pointing to. I think the suggestion of an arch, at the entrance to Queen's avenue is a good one, and it would add, as you say, interest and dignity to the approach to the Park, as well as commemorate in a most fitting manner the services of the Canadians who fell in South Africa.

Yours truly,
W. C. MACDONALD, Lieut.-Col. 48th Highlanders.

TORONTO, Nov. 14, 1900.

Honor the brave! Who desires to do otherwise? But in taking steps to perpetuate the deeds and memory of Canada's brave sons, let us not be carried away by sentiment, as the stern, stubborn facts of ways and means will confront us sooner or later.

All honor to the Red Cross ladies who are desirous of erecting a memorial arch in College avenue, as to which, the suitability and site, there would likely be little contention if we were assured that the amount required would be forthcoming, and the result be satisfactory. Let us not attempt too much for fear we fail. Past experiences should make us cautious. How much are we prepared to expend and what we are likely to accomplish, should be our first consideration. If we find a memorial arch is out of the question why should not the City Hall be the receptacle of a bronze Commemoration Panel, or one in relief, or of a piece of statuary. In mentioning the City Hall as a suitable place, might we not look forward to this building becoming the treasure house of such mementos as we may erect from time to time, either in marble, stone or bronze, a building visited by thousands of tourists annually, and a building so well adapted for the purpose.

There is no doubt that if anything is to be done now is the time, and why, I might ask, should this not be a Provincial monument? The position of Toronto is central, and the site most desirable, whether in or out of doors. Toronto, no doubt, will contribute most of the funds, but other sections of the Province should not be debarred from contributing their quota to a monument in which they are as much interested as ourselves.

R. Y. ELLIS.

TORONTO, Nov. 1, 1900.

"From the earliest times to the present day the deeds of kings and heroes have been recorded in arches of stone. The Propylea at Athens, the arch of Constantine at Rome, the arch of Triumph at Paris, the Washington arch in New York, and the marble arch in London are familiar examples of this fact. These memorials have been the means of perpetuating the memory of men and events which would otherwise have passed into oblivion. Such commemoration, recording the gratitude and appreciation of the nation, incites to great deeds and emulation in those living and in generations yet unborn. These memorials fix in the mind the sacrifices of a people on the altar of patriotism as nothing else can. They become objects of patriotic pilgrimage, and from them emanate influences which contribute to the fostering of national ideals which make for the upbuilding of the nation.

Canada has taken her place among the nations of the earth, and has demonstrated that she is an integral part of the British Empire. Shall we not record the deeds and the daring of her gallant sons? Shall we allow the names and the sacrifices of our fallen comrades to be forgotten? They have not died in vain, for their blood has cemented the structure of the British Empire.

The city of Toronto, as becomes the capital of the great province of Ontario, is adorned with statues and memorials of Ontario's illustrious dead. Shall we not rise equal to the importance of the occasion and erect a Provincial Arch of Triumph to her victorious sons, and to record for all time the names of the gallant dead who fell in the defence of the Empire and in the sacred cause of civil and religious liberty in South Africa.

I propose the formation of a committee to be composed of representatives of the Red Cross Society, National societies, the military element and representative men in Ontario to take the matter up and bring it to a successful issue.

G. STERLING RYERSON.

DEAR SIR,—In reply to your article re Soldiers' Memorial, I agree that some steps should be taken to express our gratitude for the sacrifice those brave boys made in giving up their lives for our country, and no more fitting monument could be erected to their memory than a permanent arch at the entrance to Queen's Park avenue.

I would therefore suggest, if this idea finds favor, and it surely must, that the architects and artists of Toronto be requested to

submit designs (with specifications as to cost). These designs to be placed on exhibition and competent judges apppointed—judges above approach and reproach—to select the best and most suitable one. Then a fund might be started by the citizens to defray expenses.

Yours truly,
McGILLIVRAY KNOWLES, R.C.A.

DEAR SIR,—I regret that owing to press of business I have been unable to answer earlier your letter of 8th inst. I sincerely hope that an enduring monument of some character in honor of the work of the Canadian Contingent in South Africa will be erected, but I should regret if it took the form of an arch unless a large sum of money, somewhere between $25 and $50,000 could be raised, which I think is out of the question. In any event I do not think that an arch at the entrance to the avenue in question would be desirable. A bronze statue in the uniform worn by the Canadian Soldiers in South Africa would, in my opinion, be much more readily accomplished in view of its cost.

Yours truly,
B. E. WALKER.

TORONTO, November 17th, 1900.

Dear Sir,—I am much obliged for your letter of the 8th, instant with accompanying proof of the article which is to appear in the November number of the "Canadian Architect and Builder." I am quite in accord with the suggestion made therein and am glad to observe that a movement is already on foot in Halifax for the perpetuation of the memory of our soldiers who fell in South Africa, by some fitting memorial.

Yours very truly,
F. W. BORDEN.

Ottawa, 19th November, 1900.

ARCHITECTS' AND ENGINEERS' NEW ROOMS.

The Ontario Association of Architects from date of 15th Nov., are going to have a local habitation, in pursuance of plans laid before and endorsed by the last convention. The second floor of Nos. 94 and 96 King street west have been rebuilt by Messrs. Darling & Pearson, and adapted to the requirements of architects' and engineers' association rooms—to be used for the furtherance of the interest they have at heart—the personal intercourse, interchange of ideas, and criticism of methods, which makes for that atmosphere in relation to these matters which mark the larger centres, which broadens and refines as opposed to narrowing isolation.

The entrance from the street is not all that was promised. Existing leases prevented the carrying out of the terra cotta front for the present, but passing through a massive oak door and ascending an oak stairway, at the landing is entered the lobby, or ante room, common to both engineers and architects. This is an effective square hall, twenty feet wide with unique prismatic ceiling light. The woodwork, including impost of large cove to ceiling, is all white, excepting a tint on the cove, a strikingly effective wall paper in green and blue, yellow, and red mahogany doors, with old brass furniture. From this ante room (which is to be furnished as a comfortable common meeting ground or 20x40 feet; architects' room, 20x20 feet; Engineers' room, 20x19, all members) are five doors, giving access to assembly room, a lavatory filled up in marble; a cloak room with sink and gas range, and large enough on occasions for serving luncheon or dinners. The assembly room will seat 125, is finished in white enamel, except high dado of sheeting covered with crimson burlap for tacking up drawings on exhibition. A raised dais and blackboard marks the speakers' end. The ceiling is a segment of a circle supported by heavy cambered beams.

The architects' special room has three windows looking on to King street; it has a great mantel, a book case with leaded glass doors, a fixed seat and desk, shelf and picture mould carried entirely around the room, giving continuity to the whole effect. The finish of woodwork is an antique green stain, harmonizing with reddish brown wall paper of bold pattern. Massive oak table and chairs, chosen for comfort most of all, black iron dogs set in brown tile hearth, with Turkish rug on the floor and warm curtains on the windows, completes the furnishing of the room.

The lighting of the entire floor is by electricity and is made very effective, especially in common lobby with its eight ceiling drops.

The members are earnestly urged to make use of the rooms on all possible occasions. The furnishings are not yet complete, but it is the intention that their homelike character will make the rooms a congenial place of meeting—to have on their tables and shelves such periodicals and books as will illustrate the world's architecture and art, and keep the members in touch with it.

Branch Office of the CANADIAN ARCHITECT AND BUILDER,
Imperial Building.

MONTREAL, November 16th, 1900.

CANADIAN SLATE.

Since 1893 the production of slate in Canada has gradually been decreasing, and one by one the different quarries have closed down until now there is not a slate turned out in the whole Dominion. This regrettable state of affairs was brought to a climax last May when the quarries of the "New Rockland Slate Co." were shut down. Their quarries have been the only ones working for the past two years, and as the slate turned out has almost invariably been of a uniform good quality, it is with regret that we draw the attention of our readers to the fact, and trust that soon we may hear of their starting work once again. These quarries are situated in that portion of the Province of Quebec commonly called the Eastern Townships, and have given employment to over 80 hands almost continuously since their first opening in 1864. In 1882 the company re-formed under new management, and in 1886 constructed a tramway to connect the quarries with the Grand Trunk Railway, a distance of over four miles.

The United States has recently opened up quite an extensive export trade both with Great Britain and Australia, and it is a great pity if this field for slate cannot be held in the near future by Canada.

The United States in 1898 produced for home consumption slate valued at $2,353,465, and exported $1,370,075 worth, of which $1,213,377 went to great Britain. Surely this market is worth gaioing.

There have been some improvements in slate quarrying of recent years, chief and foremost being the use of the channeler, a machine which takes the place of blasting—a process which has always been more or less objectional as it shatters and wastes a good deal of otherwise good slate. The slates from the Rockland quarries have always worn well and have proved of superior quality, and compare most favorably with the best Welsh and Pennsylvania slates. The chemical composition is as follows:

Silica S_1O_2	65.39
Alumina	15.97
Ferrous Oxide	4 66
Lime and Magnesia	3.66
Potash and Soda	6.93
Maryonous Oxide	0.39
Loss by Ignition	3.26
	100.26.

This analysis shows at a glance how rich the Rockland slate is in the valuable constituents of a slate, viz., the silicates of iron and aluminà, and if sufficient slate of the highest grade can be found, we can see no reason why an export trade could not be obtained both with Great Britain and Australia, and also probably South Africa.

FIRE-PROOFED WOOD.

The Electric Fire-proofing Company are at the present time erecting buildings near Montreal in which wood is to undergo a process whereby it will become non-inflammable. The result is obtained by forcing sulphate and phosphate of ammonia into the wood by hydraulic pressure, and has been found very satisfactory in so far that the wood only carbonizes and fails entirely to ignite. This non-inflammable wood has been used to a large extent on nearly all the more modern U. S. warships, and in a report from the Naval Constructor to the Secretary of the Navy in March, 1899, he says, after testing for eight months: "That so far as is known there is no better process of fire-proofing wood in use than that now employed by the Electric Fire-proofing Company, and its continued use, for the present at least, is advised."

The science of fire-proofing has of late years been carried to a point not dreamt of ten years ago, and at last architects are beginning to understand that no structure should be called fire-proof unless it is so in every respect. It is almost as sensible for a farmer to build a fence and have the gate open as for a man to build a large building only partly fire-proof. Architects should be more careful of their reputation than to allow a building not completely fire-proofed to be designated a fire-proof structure. Only a small portion, the underside of a steel beam or a single column, unprotected, might cause serious loss to almost the whole building. This fire-proofed wood forms the last thing necessary in fire-proof materials, as there is brick and terra cotta for the walls, porous terra cotta and concrete for the floors and partitions, encasing steel if necessary, and now there is non-inflammable wood for doors, sashes, and fixtures. These materials if employed in a scientific manner, ought to make a completely fire-proof structure, that is, one that is capable of standing a severe fire and water test.

OBITUARY.

One of the landmarks of the building industry in Montreal has recently been removed in the person of the late Mr. Charles Sheppard, whose portrait accompanying this article will be recognized by a wide circle of acquaintances. Mr. Sheppard came to Montreal in 1860 and entered into co-partnership with Mr. Henry Bulmer as manufacturers of building brick. They acquired large tracts of land in the east end of the city, and from a modest beginning their establishment grew to be the largest and most extensive of its kind in the Dominion. The firm of Bulmer & Sheppard continued until 1885, a period of twenty-five years, and then Mr. Charles Sheppard purchased Mr. Bulmer's interests, carrying on the business alone until failing health about three years ago decided him to retire from active pursuits. Since that time his two sons, George J. and Edmund, both well known to the community, have conducted and succeeded to the business. Mr. Sheppard passed away on the 12th of October, leaving a sorrowing widow (who had but a few short weeks before celebrated the anniversary of their golden wedding) and his two sons.

THE LATE MR. CHAS. SHEPPARD.

His death removed from amongst us one more of the staunch men of the old school—a man of honor and probity. One of the most touching tributes to his memory was a handsome pillow of flowers which his numerous employees placed upon his grave, bearing the inscription "Le Maitre." Mr. Sheppard was always ready, in an unassuming way, to assist the needy, and an appeal to him always met with a substantial response.

THE GRANBY ENAMELWARE CO.

The popularity of porcelain enamel iron for all sanitary ware has tempted the Granby Enamel ware Company, of Granby, Que., to start manufacturing enamel baths and sinks. The first baths turned out were slightly defective, both in the flow of the enamel and also in the finish to the edge of the rim, but in the baths now turned out these defects are being overcome. The market for these goods is very extensive in Canada, and we wish the company success in their venture, they being the first as far as we are aware in this line. We trust that the firm will bear in mind that it is indispensable to success that every detail should be carried out with the greatest care, and that no defect should be found in their first quality goods. It is often what may appear a trifling blemish that is the cause of dissatisfaction, and this soon ultimately turns what might have been success into failure.

MINES OF THE PROVINCE.

The following is a summary statement of the yield of some the mines in the Province of Quebec for 1899, that may be of interest.

Nature of Material.	No. of Men Employed.	Gross Value.
Bog iron ore	800	$40,000
Asbestos	900	581,667
Asbestic		17,069
Slate	75	30,119
Flagstones	9	3,500
Granite	60	14,780
Cement	50	31,130
Lime	250	149,000*
Bricks	1200	600,000*
Building Stone	350	250,000*

*Estimated.

The asbestos came chiefly from Megantic and Richmond Counties, the slate from New Rockland, (the quarry at that time was working), flagstones from Dudwell, granite from Stanstead, where there are three quarries, and from St. Philippe, where the Laurentian Granite Company's quarries are situated. There is also work started at Mount Johnson, in Iberville County, where a dark grey granite of good texture has been found. The cement came from Hull and Longque Pointe near Montreal, while the bricks came chiefly from Montreal, Laprairie and St. John Deschaillons.

THE P. Q. A. A.

The Province of Quebec Association of Architects will have a special general meeting on the 15th of January, 1901, in Montreal. Object: Amendments to by-laws and election of an auditor to replace Mr. C. Dufort, who is now a member of the council. Members wishing to amend any article of the by-laws should send in their proposal of amendments to the secretary before the 15th of December next.

THE NELSON MONUMENT.

This monument, erected nearly a century ago to commemorate the battle of Trafalgar, has recently undergone repairs, under the direction of the Munisinatic and Antiguarian Society, and thus restored, was recently unveiled by Lord Strathcona.

NOTES.

Mr. James Ballantyne, the well-known plumber, has recently admitted to partnership Mr. R. F. Oilvy, under the firm name of Ballantyne & Co.

A memorandum recently found in the desk of ex-City Building Inspector Lacroix is said to prove that he retained over $7,000 in fees for building permits, which should have gone into the city

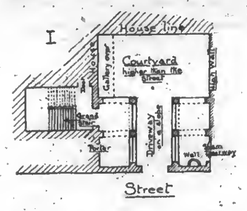
DECISION OF AN IMPORTANT COMPETITION.

Last year the corporation of the town of Levis, province of Quebec, advertised for competition plans to be submitted by civil engineers for the best system of "Waterworks," and "Sewerage" for the town of Levis. Recently the judgment has been given in an elaborate report which indicates a careful and conscientious study of the different plans submitted. The judges were, Charles Baillairge, ex-engineer for the city of Quebec; Chas. E. Gauvin, C.E., Quebec, and Jeremiah Gallagher, C.E., director of Waterworks, city of Quebec, who have awarded the first prize of one thousand dollars to Robert Surtees, C. E., Ottawa, and the second prize of five hundred dollars to Messrs. Berlinguet and Lemay, architects and civil engineers, Quebec.

The parlor of a suburban house is hung with a pale green paper having conventional figures in pale ivory of flambeaux surrounded by garlands powdered regularly upon it. The heavy curtains that separate this room from the hall are dark green velours, through which the dull red finish of the plastered walls in the hall forms an agreeable color contrast. On the parlor floor is a heavy Wilton carpet of a floral pattern, roses on a green ground, while an Oriental rug is thrown on the polished floor in the hall. The furniture is of forest green oak in the quaint style, delicate in outline yet picturesque in form. The upright piano, in a case especially designed to correspond with the other furniture, is also forest green oak. In the hall, Flemish oak has been used for the chairs and the table and mirror frame, a pair of stag horns serving as a hat rack. A tall clock in one corner of the hall is cased in Flemish oak.

SELF CONTAINED HOUSES.

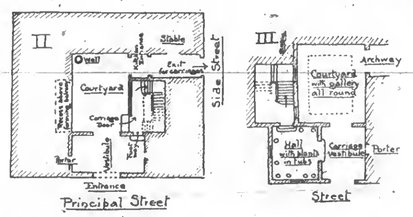
A WALK through the streets of a French or Italian town interests the imagination more than a similar excursion among the rows of houses in an English or American city where ground is precious. Everything is to the front with us. We live on the street, and even in our detached houses there is little in the block plan of the house which is of interest to the dwellers in the house which is not also in evidence to the passer-by. It is different in the southern countries of Europe. Here the highest ideal in domestic architecture is that a house should be self-contained. The more pretentious the dwelling the more it turns its back upon the street and



expands towards internal courts and gardens, free from observation, free from noise, dust and glare; and, though in the south of Europe they are apt to court shade, the same mode of planning can—which interests us most—be made to invite the sun by avoiding a look-out to the north.

The interest of the streets is increased rather than lessened by this method of building, for there is still a façade in most cases; only, instead of a flight of steps there is an archway, of which the gate usually stands open, affording glimpses of interior courts which appeal not only to the imagination but to the eye, as picturesquely diversifying the monotony of street scenery.

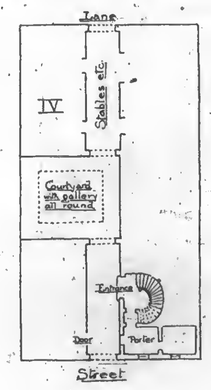
Verona is peculiarly rich in the variety of prospect thus afforded as one walks the streets. The first six plans here shown were hasty sketches made to note merely variety of entrances in that city; but there are added notes of such other keys to the plan as were



apparent to an unobtrusive observer, and the general scheme of the house is fairly clear.

No. I is obviously an interesting peep to the passer-by, as seen through the 8 or 10 foot archway. There is room for much perspective effect in the three lines of arcading backed by the open court beyond. The variety is enhanced by the fact that the driveway slopes and that the steps underneath the arches differ in number The stair is seen through an open archway beyond. There is usually no door to such a stairway; indeed there is no object in having a door for the porter is on guard, there is no exposure to the weather, and in winter the temperature out of doors is milder than that in the house. In an inn the formality of a door even at the top of a stair is often dispensed with; every man's room door is in direct communication with the street. By dint of an open fire place or a cement stove he maintains a little fortress of warmth against the cold world without, and his boots which have lain the night in the icy corridor outside are cold indeed when he takes them in again in the morning. This plan is one of the simpler arrangements; the house surrounds the court yard only on three sides, and there is no exit but the entrance, so that carriages must turn in the court and come out as they went in. The resident of a house of this description would be surprised if asked to step 5 feet across the sidewalk to his carriage, and no doubt would be astounded if he saw some of our good houses where the extent of slat walk to be traversed to get to a carriage on a rainy night is nearer 50 feet than 5.

No. II shows a larger plan in which the house surrounds the court and there is an exit to a side street. Indeed self-contained houses are usually to be found upon a corner lot where they get the advantage of a side street for the second entrance. It would perhaps be better to call this a second exit, for it is usually kept closed except on occasions when there is a procession



of carriages. Tradesmen evidently use it also in this case, as the kitchen entrance is at that point.

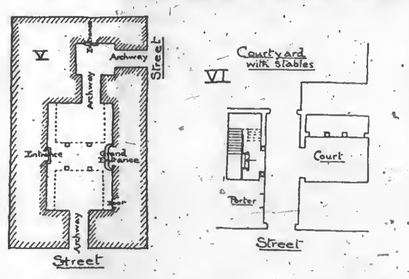
No. III appears to be the entrance of a very handsome house which has not only the second front and exit, but gets light for the hall and staircase by a return on the main front. The hall with plants in tubs makes a beautiful approach to the stairway. There is recorded in the sketch book from which these plans are taken a note upon the effect of trees or shrubs set out in a court yard with the gloom of an arcaded recess behind them. The view from the street through the hall to the staircase is probably intentional as the door to the hall from the vestibule is much larger than is necessary to mate the second door leading to the staircase, but its size just suits the needs of the raking view. The three steps at the staircase door are well placed to add interest to the vista.

No. IV is chiefly interesting as a variety of plan in which the driveway runs through the block. The distance from front to rear, measured approximately by pacing, was 130 feet. The wall on the right gives in plan a long drawn out appearance to the driveway which does not appear in execution, when the archway in the rear is seen as a distant object separated from the first archway by a field of light. The archway is 12 feet wide and the façade about 65 feet.

No. VI has a long archway, but a small court on the right admits light just at the doorway and breaks up the tunnel-like appearance that the archway would otherwise have. The absence of any probable utility for the shallow colonnade on the far side of the court and the fact that it is on the side where it will be seen, suggest the supposition that it is there for that purpose—to further relieve the monotony of the entrance.

No. V is a palace, dated 1668, in which a large court is obtained without much loss of room for the dwelling, by carrying the upper structure across the court on columns. There is plenty of room to drive between the entrance and the next pair of columns, and the height of the superstructure is about 20 feet. The main mass of building is evidently one room deep—room opening into room no doubt in the manner of the time—but passage ways are provided by carrying enclosed galleries, as shown by dotted lines, from the front and back parts of the building to the central portion which rests upon the columns.

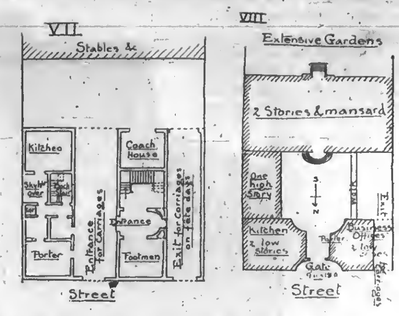
No. VII shows a Parisian residence of the best class. Here as is common in Paris the second driveway opens on the same street as the grand entrance, but there is no danger of confusion; the entrance is more imposing than the exit and the latter is kept closed except on state occasions. The house of course extends over both



openings, the full width of the lot. This is a plan for a building site which runs only to the middle of a block. If the block is shallow and the site runs through to the other side it seems to be preferred in Paris to place the the stables at the entrance and the house on the other street with its front inwards towards the court. There is none of our abhorrence of stables, and no doubt the stables are so well kept that there is no cause for abhorrence. The smaller class of houses, which have no stables and not even an entry for carriages, still make the most possible of the inside of the lot. A Parisian house of modest pretentions still attains to the dignity of facing upon ground of its own by maintaining a garden behind upon which some of the principal rooms look and where the freedom of low windows and an external verandah or gallery of some kind may be enjoyed.

No. VIII represents the British Legation at Paris, which extends entirely through a deep block so that it has not only a handsome entrance front and court but, in the true palace style, a more imposing front looking south upon a garden with no limit but a distant street. This is a splendour so remote from every-day life as to chill interest, but it is wholesome to enjoy contemplating the great problems for they do come occasionally and are apt to be abused from the very habit of not rising above the ordinary.

No. IX, which is the residence of aristocracy in a country town, is perhaps more like the sort of large treatment that would suit our needs. It is a model of quiet dignity. The front, somewhat important from the arrangement of its parts, though quite plain, has the entrance court to itself. A little lower and a little withdrawn is the service department looking into the service yard, which a lofty iron fence, like a rood screen, cuts off, while adding to rather than detracting from the

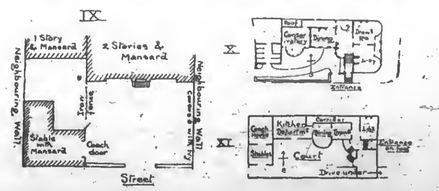


effect of its space. No doubt there is a garden on the other side of this house.

It is interesting to find that the principle of self-contained house planning was adopted by H. H. Richardson in two large houses in Chicago, shown in Nos. X and XI. Both these houses stand on corner lots. Glessner's house, No. XI, is an obvious case of getting a south aspect for a house which would, if facing the street, look north and east. The east aspect has been preserved for the library and a bedroom over the driveway, but the other rooms are made to face inwards to the court and the sun, while the street front is occupied in the most marked manner by a corridor.

In No. X, a house for Mr. Franklin McKeagh, the lot is a corner lot facing south and east so that the recess in plan does not alter the exposure but is designed for its own sake; for the advantage of a certain retirement from the street and for the increased exposure to light on the front side.

It is worth noting in conclusion that a study of foreign plans of this sort shows what a gain it would be



to the plan, how much more freedom we should have in using both fronts for living room purposes, if custom allowed the kitchen department to be put in the basement.

W. A. LANGTON.

Five bronze tablets have recently been placed in the entrance to the Massey Music Hall, Toronto, in memory of the founder, the late Hart. A. Massey, and his eldest son, Chas. A. Massey.

An historical tablet has recently been placed by the Canadian Club on the site, at No. 191½ King street west, of the Home District School, the first building used for school purposes in Toronto.

METHOD OF HOISTING A SET OF LARGE BELLS.

TORONTO, Nov. 18th, 1900.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—In answer to your request for information and a description of how the bells are to be hoisted into place in the tower of the New City Buildings, Toronto, I send you the following memos and accompanying section and plan to better illustrate my description.

There are to be three bells; the largest weighs 12,000 pounds and the other two 3,000 and 2,000 pounds respectively.

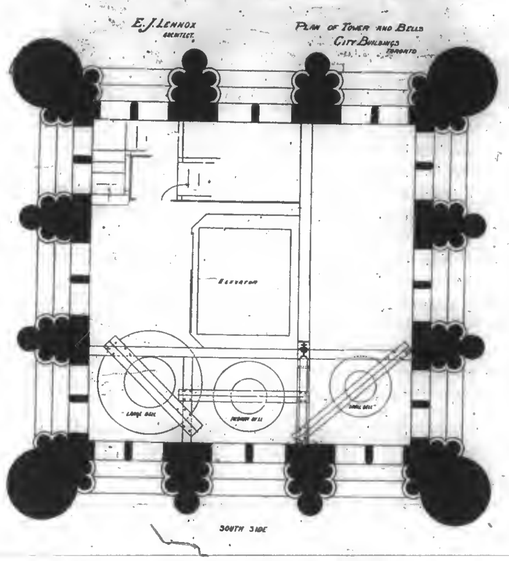
The bells have to be hoisted up on the outside of the tower to the height of about 225 feet, and taken in through the open space for the clock dials, and lowered down about 50 feet in the inside of the tower to their hanging position, which will be about 6 feet above the sills of the large open belfry windows.

In arranging for an undertaking such as the hoisting of these bells, (especially the large one), quite a problem had to be faced, for it must be borne in mind that it is a very unusual undertaking, if, indeed, it ever has occurred before that a bell of the weight of the large bell, viz., 12,000 pounds, had to be hoisted up on the outside of a building to the height that this bell has to be hoisted, before it could be delivered down into its resting place. All this trouble and expense is incurred for the reason that the contract for the clock and bells was not let in time so that other provisions might have been made for the placing of these bells. I do not, however, fear for the success of the undertaking.

I would also draw your attention to the fact that when the large 6-ton bell is hoisted it will not have been the heaviest load that has been raised to the top of the tower. One of the most precarious undertakings in the building of the tower was the hoisting of some of the finishing stones, amongst which was the raising and placing in position of the four large Gargoyles, each of which weighs 14,000 pounds, and when placed project out 9 ft. 6 in. beyond the face of the angle buttresses of the tower, and tail in on the wall about 6 feet, making the total length about 15 feet. But in the hoisting of the gargoyles I used the derrick and tackling that I had especially designed and constructed for the purpose of carrying on to completion the construction and finishing of the tower. I merely mention the fact to show that the weight of the large bell is not to be feared in connection with the hoisting, but the great difficulty is in having to undertake the hoisting of such a weight as this with appliances and tackling that can only be temporarily erected for the purpose. After a good deal of consultation between the clock and bell contractor's foreman, and sub-contractor, who has undertaken the contract to hoist the bells, and myself, the following plan has been decided upon:

THE LARGEST OF THREE BELLS TO BE PLACED IN THE TOWER OF THE NEW MUNICIPAL BUILDINGS, TORONTO. HEIGHT OF BELL, 6 FEET; DIAMETER, 6 FEET 8 INCHES; WEIGHT, 12,000 LBS.

At the top of the tower opposite the south dial will be erected a shear-legged derrick firmly planted on heavy timber base, on projecting ledge of tower, and anchored in at foot so that it will not shear out, but so formed that it will not retard the inward movement of the derrick. The head of the derrick will hang out from the face of the tower far enough to allow the bell to be hoisted clear of all projections. At the head of the derrick will be fastened the hoisting sheave rigged up with two ⅝-steel wire cables, each capable of sustaining 10 tons. These cables will extend from the top of the bell while on the ground, up to the hoisting sheave and down to the drum of the hoisting engine which will take in the slack. The top of the derrick will be anchored back at head to keep it in its outward hanging position. To the head of the hoisting derrick will be fastened another steel wire cable brought back into tower through sheaves and down to a crabwinch; this cable will be used for drawing in the head of the derrick. At a few feet below the level of the height that the bells are to be hoisted up to, before they are hauled into the tower, will be a strongly constructed, projecting platform erected to receive the bells. The platform will be anchored back into tower, projecting just far enough so that the bell when being hoisted will pass quite close to the edge of same. There will also be properly rigged-up on the inside at the top of the tower a hauling in hemp cable, capable of sustaining at least a weight of 10 tons. On the ground at the foot of the tower will be erected a steam hoisting engine and drums.



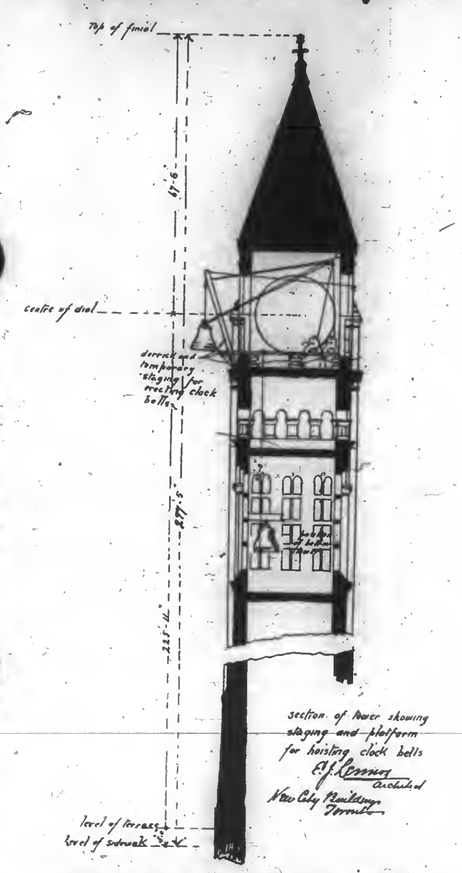
The process of taking up each bell will be, that it will be hooked on to the hoisting sheave at end of cable hanging down derrick and steadily and carefully hauled up by the hoisting engine until it reaches a height of several feet above the level of the projecting platform. Then the head of the derrick will be hauled in until the bell hangs over the platform, when it will be gently lowered down on to rolling skids, and pinched into the required position.

The bells having reached this position it will be an easy job to lower them down into their place with overhead tackling hung from beams in the top part of the tower; they will then be blocked up into position until they are bolted up to the heavy framework of steel beams, when blocking will be removed and they will hang clear fastened to beams.

In conclusion, I might say that every precaution is to be taken; the scheme has been carefully thought out, and I have no reason to think other than that the bells will be carefully landed and swung safe and sound into their position without accident.

Yours sincerely,

E. J. LENNOX,
Architect.



ENGINEERS' CLUB OF TORONTO.

The meeting of the Engineers' Club for November was held at the new club rooms which have recently been fitted up at 94-96 King street west. About thirty members were present. Reports of several committees were received.

Mr. T. B. Speight tendered his resignation as treasurer, owing to the fact that he expected to be absent from the city for several months. Mr. Canniff was appointed as his successor.

The following committees were appointed:

Finance Committee—Messrs. H. F. Duck, Jas. McDougall and A. F. McCallum.

House Committee—Major Gray, R. J. Parke, and A. B. Lambe.

Library Committee—Messrs. W. T. Jennings, W. H. Patton, and W. A. Clement.

A resolution of thanks was voted to the proprietors of the Rossin House for providing a room for meetings of the Club during the past year.

Notice was also given of several proposed amendments to the Constitution which will come up for discussion at the next regular meeting.

The Canada Asphalt Paving Company has been incorporated, with headquarters at Montreal. The capital stock of the company will be $50,000. The incorporators are Messrs. R. L. Dillon, J. St. G. Dillon and A. P. Dillon of Montreal, and James A. Pearson, A. W. Godson and J. H. Denton of Toronto.

METHOD OF CONSTRUCTING A WOODEN ELEVATOR.

The erection of a modern elevator is a task of no little magnitude, and entails many different principles of construction.

Though the steel framed elevator is now commonly used and seems to the architect of other modern build-

No. 1.—(A) Cement Piers. (B) Sized Lumber Piles.

ings, to be perhaps the only correct method of construction for such enormous erections, yet some of the largest elevators in the Dominion and elsewhere embody largely the simplest and earliest methods of construction.

The accompanying illustrations show very clearly this method of building—substantially that of the settler of the primeval wilderness when he puts up his log cabin.

This is one of the largest sized elevators, yet its builders claim for it advantages which, on the whole,

No. 2.—Shows Tratelling Cranes and Method of Erecting Trusses.

cannot be surpassed by any other character of building. It is much cheaper than the steel building in material, and its cost in erection is far below that of the other. Its rigidity is remarkable, and the dangers from side thrusts are entirely obviated.

Grain in bulk, wheat particularly, asserts great side thrust, being in reality a semi-fluid, and acting similar to water. A glance at illustration No. 5 will show how entirely this force must be overcome, the building being so bound together by its own divisions and bins as to be incapable of crushing, and bulging being impossible.

The illustrations are from photographs of the work upon the new I.C.R. elevator in St. John, N.B., and show very clearly the character of construction, method of operation, and, by the dates in the corners, the progress upon the work. This building was erected by Mr. J. A. Jamieson, of Montreal, who is perhaps the best known elevator builder in Canada, and has the reputation of being a most up-to-date contractor and designer in this line.

While the foundation was being prepared a mill was being fitted up with machinery immediately adjoining for the cutting up of the lumber into the various sizes required. This work was completed and the lumber

No. 3.—Sub-Timbering Complete—Planking just Begun. (A) Mill belonging to the Works. (B) Sized Planking. (C) Lumber Slides—fitted with Rolls

stacked in sized piles all ready for use before the construction began.

This method greatly facilitates matters, as the construction is proceeded with almost mechanically in its various stages.

No. 1 illustration shows one of the 98 cement piers in the foundation. No. 2 shows the character of the timberwork (Georgia pine) resting upon these, and illustrates the methods and simplicity of its erection.

The trains of cars are run into this lower part of the completed structure, and it also contains much of the machinery requisite to the elevating. From here up-

No. 4.—Illustrating Sub-Timbering, Plank Mid-Structure, and Timbering of Superstructure.

to what might be termed the clerestory, the entire structure is of 2x7 spruce planking, laid on the flat and spiked every few feet alternately near the opposite edges with 5-inch wire nails.

No. 3 shows the first few courses of this planking laid, and shows the lumber carriers, made up of a series of horses fitted with rolls, which may be seen more clearly in No. 5. The lumber is elevated to these

carriers at one end (the farther end in No. 3), and is then shoved along horizontally to its desired position. As the structure rises layer by layer, the carriers are elevated accordingly as often as necessary, being so designed that they interfere none whatever with the work, as is shown in No. 5. This is a peculiarly designed carrier and a most effective one.

No. 5 also illustrates the platforms for the workmen and the character of their supports in such a way as to be almost needless of explanation. The wedge brackets can support the platforms at any height as the work

No. 5.—(A) Wedge Brackets. (B) Wedge Brackets in Service Supporting Platforms. (C) Movable Platforms. (D) Lumber Slides in Position. (E) Rolls.

proceeds, and these are raised as fast as the planking rises.

Close inspection of the picture shows that cross and longitudinal layers of plank lap alternately. This view is taken at a height of 60 or 70 feet from the ground.

No. 4 shows the exterior of the planking when completed, the perpendicular lines being the ends of the cross planking. It is now ready for the galvanized iron covering which makes the outside finish.

A. B. Pickett.

Oct. 31st, 1900.

THE INTERCEPTING TRAP.

The Builders' Journal, of London, reproduces the correspondence lately published in these columns on the above subject, and comments thereon as follows :—

"Our readers will probably be astonished, not so much at the diversity of opinion, as at the backward state of sanitation in our great colony which these reports appear to indicate. True, our sanitarians have not yet discovered the best method of ventilating sewers, for indeed ventilation, whether of rooms or sewers, appears to be the most difficult subject with which the modern engineer has to deal; yet we thought by this time it was a generally accepted principle that the house-drainage system should, as far as possible, be separated from the main sewerage scheme. But apparently the Canadian system in the past has been to ventilate the main sewers by means of "breathers" or gratings at ground level in the front gardens, and it is hardly surprising, therefore, that our Canadian confrères are desirous of altering a condition of things that is both dangerous and unpleasant. At the same time to make the soil pipe the means of venting the sewer air does not by any means lessen the danger, for only the water seals of the water-closets and gulleys prevent the ingress of sewer air into and round about the house. If, as several of the writers point out, the tops of the soil pipes are frequently choked by frost, any pressure of the sewer gas will force the water seals and enter the house. This new evil would probably be worse than the original trouble. If the sewers are to be ventilated, they must be ventilated below the disconnecting trap, so that no possible danger of sewer gas forcing its way into the house system may be apprehended.

AN ATTEMPT TO BRIBE ARCHITECTS.

The following correspondence has been forwarded by Messrs. Burke & Horwood, architects, of Toronto, in the hope that its publication may deter other manufacturers from adopting a like foolish line of policy. The words underscored were underscored by the United States firm who are the authors of the proposition.

(Copy).

Racine, Wis., 11—1—1900.

Messrs. Burke & Horwood, Toronto, Ont., Can.

Gentlemen: We note through the different contractors' journals, that you are designing and constructing many buildings. We believe there is much of mutual interest in our profession and line.

We wish to inform you and make you familiar with our entire system, so that in the planning and construction of your work you can recommend some of these devices which seem most practical, and for every building that is equipped through your recommendation and plan, you are to receive 5% on the contract price.

We would be pleased to have your views regarding this plan. We now have two or three hundred architects working with us, and we propose interesting the majority of the leading architects of the entire country. You can give us the name of the parties with whom you are dealing, or furnishing plans, and we will correspond with and give them all the information possible, and with your consent refer them to you, as a disinterested party as to your views on the subject.

Hoping to receive a favorable expression from you, we are

Yours very truly,

Racine Fire Engine & Motor Co.

R. B. Sigafoos, Pres.

We are not members of the Fire Apparatus Trust.

(Copy).

The Racine Fire Engine & Motor Co., Racine, Wis.

Dear Sirs,—Yours of the 1st inst. is received, asking us for our views regarding certain statements in your communication.

In the first place, we have to state that you are making a great mistake in offering a commission. No reputable architect will have anything to do with such a proposition; it is entirely against all the best traditions of the profession.

Second—an architect who accepts such a commission cannot be a "disinterested party."

If your goods are what you claim for them, they should carry their own recommendation without the necessity of a bribe to the man who should, of all others, judge by the merits of the article he is recommending, from an entirely unbiassed standpoint.

Our advice to you would be to send out no more such offers to the profession, if you want to retain the good will of all right minded architects.

Yours truly,

Burke & Horwood.

Architect—"We've settled about the design for the drawing room. Now, as to the study; how do you want that finished?"

Nurox—"I seen in a newspaper once about a study in black and white that was very artistic. Suppose you gimme one o' them?"—Philadelphia Press.

NOTES ON THE FIRE AT PARIS, ONT.

In answer to enquiry, Mr. John Kay, architect, of Paris, Ont., has kindly supplied the following notes on the recent destructive fire in that town :

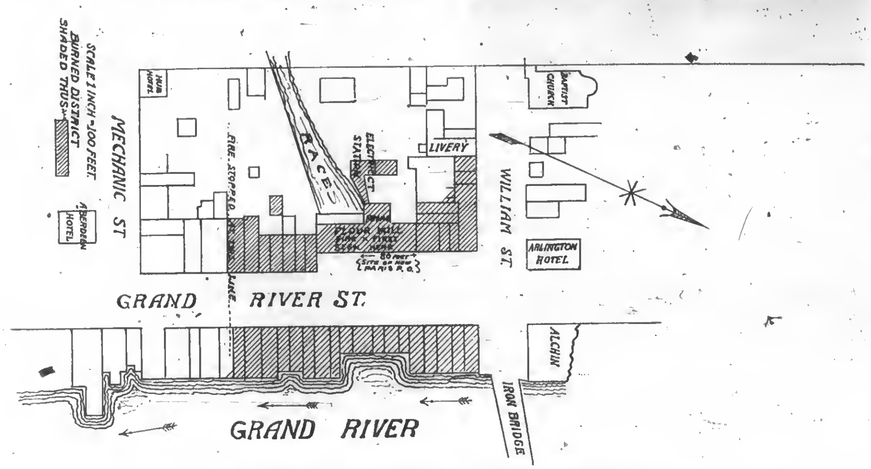
"As to our big fire on the 12th inst., it started in Mr. Meldrum's flour mill, a frame building 150 feet long by 45 feet wide, posts 30 feet high; posts 8 feet apart, 12 x 12 ; beams and posts in centre, 12 x 12 ; joists, 4 x 10 ; shingled roof with a cupola, 10' x 14', 6' high on top of ridge, with louvres which acted as a chimney. This caught fire, and in a short time the flames were everywhere—first breaking the glass and leaping up the clapboards. I never saw a better constructed fire with a gale from the west estimated at a 50 mile gait.

The fire blew across the street and the plate glass melted and ran like molasses. The stores along the east side of Grand River street were first class—some rooled with slates, but mostly metal (Garry iron) laid on tarred felt ; plate glass windows. Patton's hardware store was next the mill on the north side. Kegs of nails were fused into one solid mass. The embers flew across the Grand River, and set on fire the dwellings on the opposite side of river. The floor of William street iron bridge 130 yards long was on fire in many places ; a bucket brigade managed to save it. The mill in question was built 50 years ago and the building sites are few (the lower town where the fire occurred being in a hollow with hills around three sides and the river on the east,) and buildings were close up to the mill in front and on each side. The heat was so great that the water thrown with 80 lbs. per sq. inch seemed to go up in steam before it had a chance to put the fire out.

The town by-law forbids the rebuilding of such a structure as this mill. Brick and stone can only be used in walls. Paris previous to 1832 was called the Forks of the Grand River, since then it has been Paris. The mill in question was built in 1842 about 10 years before the railway reached the place. I am safe in saying that every building burnt on the 12th of September has been erected since the mill was built.

Paris has had fires in stores but the firemen managed to keep the fire within the walls where it started. In Randal's block there were three different fires without much damage to brickwork. This time, however, the lintels are so burned that the whole front will require to be taken down and rebuilt on new timbers.

Find enclosed a sketch showing position of burnt buildings. Already men are at work clearing out the cellars. Brick walls will take the place of lath and plaster partitions. Although lumber and hardware is dearer, money is cheaper. On the whole I am of opinion the fire was a blessing in disguise. A fine new Post Office, Custom House and Inland Revenue Building will occupy the site of the old mill. Pressed brick fronts with stained mortar will supersede the Princeton bricks. More vaults will be built—the contents of some of the so-called fireproof safes were worthless. Prism glass will be used to throw the light to the rear of the stores. The new buildings will have a proper grade corresponding with the centre of Grand River street. Before the fire the sidewalk would be level with the door sill of one building while next door the sill would be 8 inches above the sidewalk, and so on, giving the streets a very unseemly appearance.



Sketch Showing Burned District at Paris, Ont.

PERSONAL.

The sympathy of a wide circle of friends is extended to Mr. John H. Tilden, president of the Gurney-Tilden Co., of Hamilton, who has recently been bereaved of his wife.

Mr. P. W. St. George, city surveyor of Montreal, has tendered his resignation on the ground that he can no longer put up with the interference and discourtesy of the Road Committee. Mr. St. George has been in the employ of the city of Montreal as deputy city surveyor and city surveyor for a quarter of a century.

STUDENTS' DEPARTMENT.

C. A. & B. STUDENTS' COMPETITIONS.

The publishers of the Canadian Architect and Builder invite architectural students and draughtsmen resident in Canada to submit drawings in the following competitions:

STUDENTS' COMPETITION FOR A PORCH.

A plan, section and perspective sketch are required. Explanatory detail sketches of certain portions may also be included.

The subject is an entrance porch to a city house of 35 feet frontage facing south or east on a 50 ft. lot. The porch to be large enough for use as a verandah, and yet not to cover all the front windows, as it is desirable to have the sunshine enter the parlor by at least one window.

The porch may be of wood, brick or stone or combinations thereof and may have flat or sloping roof.

STUDENTS' COMPETITION FOR ENTRANCE DOOR, VESTIBULE AND VESTIBULE DOOR.

A plan, and section are required and elevations of both doors.

Explanatory detail sketches of certain portions may also be included.

The subject is the entrance from the above mentioned porch. Light may be obtained for the vestibule from a window on one of the walls not occupied by the doors, or from the entrance door or wall in which the door is placed.

The vestibule must be large enough to accommodate a fair sized hat rack and an umbrella stand.

Drawings must be made with pen and perfectly black ink on white drawing paper or cardboard. No brush or color work will be allowed. Drawings should be so arranged as to admit of photographic reproduction in the illustration pages of the Canadian Architect and Builder. The size of each page is 7x10 inches. No set of drawings must occupy more than two pages.

Competitors must send in their drawings, prepaid, under motto marked "Students' Competition," and addressed to "the publishers of the Canadian Architect and Builder, Confederation Life Building, Toronto," prior to 5 o'clock p.m. of the dates set for the competition, viz ; 1st competition, Thursday, 27th December, 1900 ; 2nd competition, Monday, January 28th, 1901. Each set of drawings must be accompanied by a sealed envelope bearing on the outside the author's motto and enclosing a card giving his full name and address.

The merits of the designs which may be submitted in in these competitions will be judged by a committee of the Ontario Association of Architects, whose decision shall be final. For the benefit of competitors, the judges will be requested to give a detailed criticism of each design.

Three prizes are offered in each competition as follows : To the winner of 1st position, $10 ; to the winner of 2nd position, $5 ; and to the winner of 3rd position, one year's subscription to the Canadian Architect and Builder.

The right is reserved to publish any or all of the drawings.

Note.—Competitors are required strictly to observe and comply with the above instructions and conditions.

EXHIBITION OF ARCHITECTURAL DRAWINGS.

The members of the Toronto Architectural Eighteen Club have made all arrangements to hold their first annual exhibition from January 26th to February 9th, 1901, at the galleries of the Ontario Society of Artists, King street west.

The above Club joined the Architectural League of America nearly two years ago and have been working on having an exhibition of American and Canadian drawings ever since. The success of the exhibition is assured ; not only has every American club promised to give every assistance, but also many of the leading architects and the following gentlemen have kindly consented to look after the Eighteen Club's interests in their various cities : Adin B. Lacey, Philadelphia ; N. Max. Dunning, Chicago ; Chas. D. Maginnis, Boston ; Edwin G. Gardin, St. Louis ; Gustave W. Drach, Cincinnati ; Julius F. Harder, New York ; John T. Comes, Pittsburg ; Percy Ash, Washington ; Prof. Newton A. Wells, Urbana.

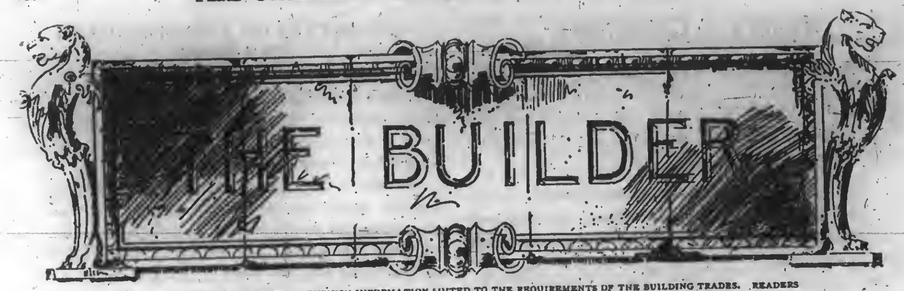
Beside the various drawings which the Eighteen Club will receive from individual architects and draughtsmen from the United States and Canada, there will be an exhibit of circuit drawings of the Architectural League of America consisting of about one hundred and twenty-five of the best drawings made during the year. An illustrated catalogue will be issued and distributed free to Canadian architects, and it is the desire of the Toronto Architectural Eighteen Club, that every architect in Canada will send in his name and address to Ernest R. Rolph, secretary, Bank of Commerce Building, King st. Toronto, as it is only through the medium of this publication that they can be reached, and for that purpose have inserted an advertisement on page vii.

The above Club is issuing a special circular with all information re this exhibition, along with invitations to all Canadian architects and draughtsmen to contribute drawings, and it is hoped there will be brought together the best collection of Canadian work ever seen.

THE TORONTO HOTEL.

The announcement is made that the financial arrangements necessary to insure the erection of the proposed Toronto Hotel, have been completed, and that contracts for the construction of the building have been awarded. The plans for this important building have been prepared by Mr. Henry Ives Cobb, of Washington. The building will front on King, Victoria and Colborne streets, the main entrance being off King street. There will also be a second entrance off Victoria street. These entrances open into a rotunda 80x90 feet. The remaining frontage on both these streets will be fitted up as shops. The general dining room, banquet hall, assembly room and state apartments will occupy the first floor. On the succeeding five stories will be sixty bed-rooms with forty-two bath-rooms. The total cost of the land, building and furniture is placed at $1,500,000. Aside from the public need which this building will supply it promises to form an important addition to the architectural features of the city, and a help in maintaining values of business property east of Yonge street.

J. C. Killam & Co., of Moncton, N. B., who have secured the contract of strengthening, readjusting and covering the Memrancook bridge are now at work upon it. This firm makes a specialty of bridge building and have built quite a number in Nova Scotia and New Brunswick. They built the Long Creek bridge in Queens County, N. B., last summer.



[THIS DEPARTMENT IS DESIGNED TO FURNISH INFORMATION SUITED TO THE REQUIREMENTS OF THE BUILDING TRADES. READERS ARE INVITED TO ASSIST IN MAKING IT AS HELPFUL AS POSSIBLE BY CONTRIBUTING OF THEIR EXPERIENCE, AND BY ASKING FOR PARTICULAR INFORMATION WHICH THEY MAY AT ANY TIME REQUIRE.]

For the Carpenter and For the Mason.

Both carpenter and mason are often confronted with problems in arched work. The first, because it is his duty to make all centers and frames required to be built even or round, the second, because it will be necessary for him to obtain the proper bevels and lines for forming the voussoirs and key-stones of his work. The construction of centres may safely be left for future consideration, providing the manner of obtaining the outlines of the work be fully grasped by the operator. It is generally the carpenter who prepares all the paterns for the mason, and who lays out the radial lines and the curves for both exterior and interior, but there are occasions when the mason is compelled to obtain the lines for himself. The following illustrations are arranged to suit both craftsmen.

Elliptical Arches.

At Fig. 1. an arch is shown which is semi-elliptical, and is drawn by means of a trammel, or by aid of a string, as has been described in this department in previous issues. The arch is divided into sections or blocks of the proper size, and this is done by first dividing the curve into any desired number of equal spaces, then, wherever the joint is required, first draw a tangent to the curve from which square draw a line touching the joint where the joint is wanted, and this will give the proper radial line as shown at s. Fig. 2 shows a Tudor gothic arch formed by two parts of an ellipse. The manner of getting the curves for this arch is shown by the dotted lines, where the two rampant semi-elliptical arches are displayed. The curves are obtained by the same method as described in Fig. 1, and the lines of joints are found by the same method as shown in the previous example.

Semi-Circular and Segmental Arches.

To draw the lines for a semi-circular arch is a simple matter, as all the radiating lines for joints and for the keystone are drawn from a common center, o, Fig. 3. The springing line is also a radial line, being on the same plane as the center o; the illustration explains itself. Segmental arches are more difficult to lay out than semi-circular ones, as the center from which the curves and radial lines are drawn is outside of the area of the arch and its chordal lines. A method of finding the center of any segment is shown at Flg. 4. Let A B C be any three points in the arch, all we have to do is to connect A B and B C by straight lines. Then from the center of A B, and from the center of B C, square down until the lines intersect at D, as shown, then the point D will be the center of the circle of which the arch is a portion. Thus, if we make A C the points from which the arch springs, and square up from the center X, and measure the height of the arch to O, we will have the three points through which the arch will cut. This method is, perhaps, better shown in Fig. 5, where a h b show the width and height of arch. The curves c d are

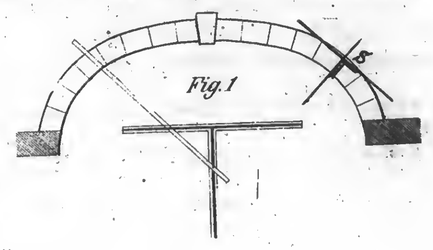


Fig. 1

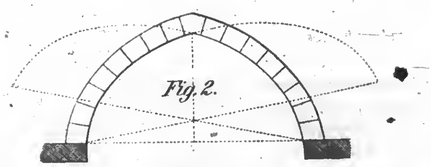

Fig. 2.

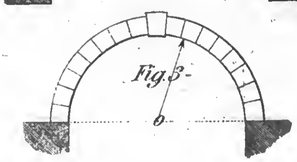

Fig. 3.

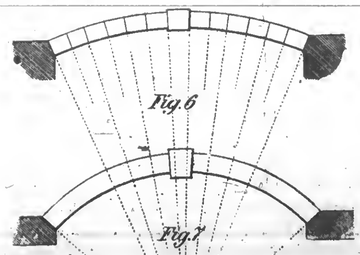

Fig. 6

Fig. 7

drawn from the center a b, and the line c d g is drawn through the points c d. The curves e f are drawn from the center a h, and the line e f cuts through the center of the required circle at g. Two segmental arches, drawn from one center o, with different radii, are shown at Figs. 6 and 7. The joints and springlines are also shown. Fig. 8 exhibits an equilatoral gothic arch. This is described by two equal radii from the points o o, as centers, and jointed from the same points. Lancet gothic arches are drawn with a greater radius, having as centers points beyond the center, o o, with he lines of the curves starting from the points as shown in the diagram. A much flatter gothic arch is shown at Fig. 9, the centers for the curves being within the span of the arch, as shown at o o. Gothic arches of any degree of acuteness may be obtained in the manner shown at Fig. 8, it only needs to use a greater radius when making the curves. The same also applies to

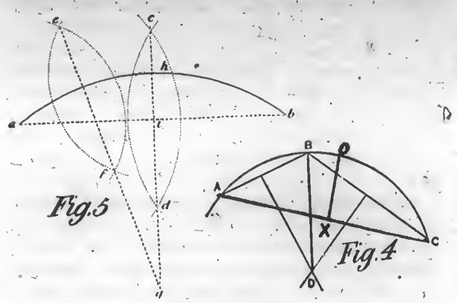

Fig. 5

Fig. 4

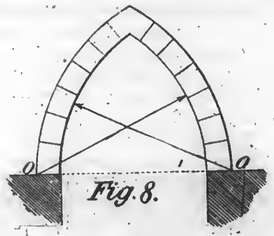

Fig. 8.

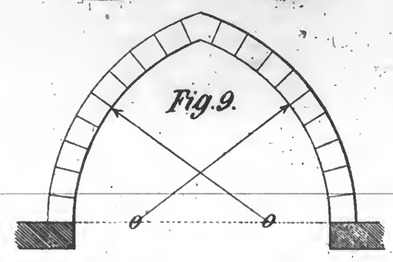

Fig. 9.

flat arches; the nearer the radius is to a semi-circle the flatter the arch will be.

Other Arches.

Besides the arches we have illustrated, there are many others, among which may be mentioned, flat arches, of which there are various styles, and which are used over square top sash and door frames, and for lintels over open fire-places, and other similar purposes. There are also various kinds of Moorish or horseshoe arches, and of arches with semi-circular soffit, and a gothic outline outside, also rampant or raking arches, skew arches and arches that are inverted, as well as relieving arches. There is also an arch called the winged auch, in which the voussoirs are continued on horizontal line of the spring to some distance beyond the face of the inside wall or jamb. The different styles of arches and the manner of working them, and obtaining the lines for their construction, will form ample material for further comment. There are other classes of work, such as forming arched windows in circular walls that will surely be of interest to those engaged in the construction of buildings. To the carpenter, a thorough knowledge of lines pertaining to such work as has been described in these pages, is indispensable, for on him devolves the duty of laying out pretty nearly all the work of a constructive nature about a building.

THE LATE G. H. WALLACE.

The death of Geo. H. Wallace, contractor and builder, of Sussex, N. B., is to be deeply regretted in the trade, which loses thereby one who has been eminently respected at all times and who took an active part for many years in the building up of his province.

The Late G. H. Wallace, Sussex, N. B.

The deceased was a native of Nottingham, Eng., where he was born in 1827. He received a good education, and at an early age entered the army, in which he served some years in both Scotland and Ireland.

In 1848 he came to Canada and settled in Sussex where he worked at his trade as a carpenter and builder. In late years he was a justice of the peace, a stipendiary magistrate, and in 1879 was made collector of customs, which latter office he filled until his death.

Four children survive him: Mrs. A. D. Sharp, of Campbellton, Mrs. Quigg, of Boston, and two sons, F. W. and W. H., who comprise the present firm of Wallace Bros., contractors and builders.

A new factory, 100 x 560 feet in size is in process of construction at Walkerville, Ont., for the Ontario Bridge Works. The structure will be a steel frame, fireproofed, and will cost $20,000. The company will employ 150 workmen in the manufacture of steel bridges, roofs and building material.

Attention is called to the announcement in this issue of the Imperial Varnish Company of Toronto. This company are manufacturers of high grade varnish for architectural and other purposes. Architects and others of our readers who have occasion to specify or use this material would do well to look into the merits of this company's goods.

According to Leslie's Weekly the Chinese are a nation living in brick houses in a land without a brick-making machine. All the millions of homes in the thousands of walled cities are built of brick, and every brick made by hand. These bricks are made by labor costing but 10 cents per day, still they cost more than our machine brick made with labor costing 25 times as much.

THE PROTECTION OF PUBLIC BUILDINGS FROM LIGHTNING.

MR. KILLINGWORTH HEDGES, who has been advising on the re-arrangement of the lightning conductors on St. Paul's Cathedral, recently read a paper on the above subject before the Royal Institute of British Architects. He quoted from a paper read before the same Institute by Col. the Hon. Arthur Parnell in 1884, in which an analysis of a number of disasters to buildings fitted with lightning rods showed that there were 828 separate instances of mechanical force, as against only 228 of heat, exercised on various substances by lightning. Mr. Hedges also repeated Dr. Lodge's statement that the problem does not end with the actual rod, owing to the large difference of potential existing between the conductor and earth, however well the two are connected. He expressed himself in agreement with Dr. Lodge as to the oscillatory nature of the discharge, and expressed the view that the side flash was the result of self-induction in the conductor. On one matter, however, Mr. Hedges' theory was somewhat remarkable. He considered that when a discharge occurred at one point between the thunder-cloud and earth, a corresponding discharge occurred in the reverse direction at another point of the cloud. He referred to these as the "downward" and "upward" discharges, and stated that he had frequently seen in Colorado "upward" flashes arising from the ground! In connection with available reports and statistics of lightning accidents, Mr. Hedges regretted that no official reports of this nature had been published since that of the Lightning Rod Conference in 1882.

Not the least interesting part of Mr. Hedges' paper was a description of the lightning conductors attached to several important buildings abroad. On the Notre Dame Cathedral, in Paris, the main conductors are three in number, each of the two on the towers commencing at a massive wrought-iron terminal rod about 20 ft. high and 4 in. square at the base. To this a wrought solid iron rod about 1 in. square is secured by straps, and run in lengths, jointed at intervals, over the roof and outside the tower to the ground. This rod is supported about 7 in. from the lead roof and stonework by stanchions insulated by half-round stone or porcelain insulators secured by shackles. At a later period a copper strip had been connected to each of the conductors at the roof and run independently to the ground below. The spire has an elaborate finial with numerous points and this appears to be connected to earth in a similar manner, and also to the crest running along the ridge of the roof. The speaker considered this method of protection to be a source of danger at present. The flash received by one of the main rods had two paths open, one by the old iron conductors and a second by the new copper band. The current could be prevented from dispersing over the lead roof by the insulators of the conductors, and owing to the resistance of the joint would consequently jump from the central rod to the small copper one.

On the Cologne Cathedral he considered the protection far more advanced than that of Notre Dame. Stranded copper cables are used, run through galvanised iron stanchions with flat feet by which they are bolted to the stonework. To avoid galvanic action, the eyes of these supports are bushed with lead. They keep the conductor about 7 in. away from the structure so that the cable can be stretched tight by tightening screws and not run round projections. A somewhat similar arrangement is used for the horizontal conductors which run each side of the roof and are kept away from it. The terminals of the lightning rods, Mr. Hedges continued were almost always plain spikes without branches, but German buildings had many of these both on the highest portions and along either the tops of the walls or ridge of the roof, the whole being connected together by a horizontal conductor run in the method described. A timber shed near Frankfort had these vertical rods about 15 ft. apart and a petroleum storage tank at intervals all round its circumference.

The lightning conductor of the Palais de Justice of Brussels is very similar to that of the Hotel de Ville, which has been described in text-books. It is on the Melsen system, and consists of a network of metal rods connected together at the top and furnished with an aigrette or bundle of eight 4mm. copper rods spread out like a feather, so that, after passing over the roof, the terminal points project so little that they can hardly be seen from below, yet they break up the area of the buildings and leave little space unprotected. The conductors are of copper, but where they descend a special iron box is employed in which they are embedded in zinc, and from this the down rods can be continued in iron and also connected to the rain-water pipes and other ironwork of the building. The Palais de Justice was struck soon after the lightning conductor was completed, but no more damage was done than the partial fusion of some of the points of the aigrette which received the flash.

French architects, Mr. Hedges said, seem to prefer the long single point. The standard rod or tige is 6 metres high and about 6 cm. diameter at the base, tapering to nothing at the top. The rod is firmly connected to the woodwork of the roof, and the copper or iron conductor is fixed at the base by means of a shackle. The conductor is usually kept away from the building by supports, and is carefully led into moist earth—or, in the case of rock foundations, it is connected to a network of wires running for a considerable distance under the surface. Where a well can be used, the earth connection is prepared by plaiting up galvanised iron strips to form a basket, which contains a sort of grapnel, the latter being attached to the conductor and the basket being filled with coke and lowered into the water.

The method adopted in most American cities at present, the speaker continued, is the employment of a round iron rod about half-an-inch in diameter, extending from the ridge of the metal roof about 4 ft. above the top of the chimney or other elevated projection, its lower end being connected to a piece of iron in the form of a saddle, soldered to the metal roof. To this the top of each rain pipe is joined, or, where the gutters are below the roof, special tinned iron strips connect the two. It is said that each rain-water pipe 4 in. diameter is equal in capacity to an iron rod 9-16 in. diameter. The connection between the pipe and the earth is made as follows: Above the elbow portion, a galvanised socket is fitted, and to this is soldered a flat bar which is led directly to the nearest water pipe or to the earth. The form which seems to give the best results, he said, is constructed of a pipe driven into the ground so that its perforated end rests in moist earth; its upper end is left about 6 in. below the surface, so that it can be watered artificially or by rain. To assist the collection of moisture a larger sleeve is placed outside, furnished with a perforated top and set flush with the gutter. With slate or wooden roofs, bands of tin plate or galvanised iron are often placed underneath the slate covering on the rafters of the roof, being connected at the top with the "air terminal" conductors, and below with the gutters and rain-water pipes as previously described; in the case of a Mansard roof the sheet metal or flushing is also connected to the system.

Mr. Hedges was called in, in 1898, to report on the condition of the lightning conductors of St. Paul's Cathedral. He was informed that they were put up in the year 1872, having taken the place of the original system erected under the advice of the Royal Society about 144 years ago. The conductors were throughout of ½ in. stranded copper. Four of these conductors passed from the iron supports of the cross down the outside of the dome branching into eight conductors which were cross-connected by the railing of the gallery. Lower down they were united together and carried down to the ground. Each tower had two conductors with a cross connection, and there was also a single conductor passing over the ridge of the choir to earth on either side. In the metallic connection with the cross there were several iron straps passing down inside to the level of the gallery, where the ends apparently disappeared in the stonework. This, in Mr. Hedges opinion, constituted a danger. The statues on the three sides of the building were not protected. The earth connections were also most unsatisfactory. These had originally been laid in a brick sewer passing around the building but in alterations since executed, earthenware pipes had been laid within the sewer, the brick sewer being no longer employed, and the conductors were therefore left either resting on the top of the earthenware pipe or placed within them so that they were insulated from earth. The joints were in all cases wrapped and not soldered.

The plan of re-arrangement recommended by the author, taking into consideration the large amount of copper cable already disposed about the building, was to run three new cables from the metal-work of the framework supporting the cross to the roof of the dome (making interconnection with the iron supports of the structure); there connecting them with the eight existing conductors and reuniting them at the base of the dome to the existing system, which was to be increased by running a new ½-in. seven-ply copper cable on the top of the parapet entirely round the building. From this horizontal conductor, aigrettes, consisting of five pointed copper rods, were teed at intervals by means of special brass boxes tinned inside, into which the cable was placed, the aigrettes first secured by binding, and the whole united by running in hard solder. Great difficulty was found in securing new earths. One set of conductors was united to the hydraulic main supplying the power to the organ, and the other to the 8-in. water main. This connection was made by cleaning the outside, then wrapping the strands of the conductor around it, and then enclosing the whole in a metallic clamp which was filled with molten lead and screwed up tight. An additional earth was made by means of a perforated wrought-iron pipe furnished with a steel shoe, which was sunk to the requisite depth to secure moist ground. The stranded conductor was dropped into the pipe, soldered to a lead cap on the top, and shielded from electrolytic action by wrapping it in a lead tube. The pipe has a bend at the upper end, projecting above the ground and closed by a plug so that water can be poured down. There are other earths of ordinary copper plate buried in a mixture of charcoal and broken electric light carbons, and the old system of conductors, as well as the new, is attached to all the new earths. It is also proposed to establish connection with the ends of the rain water pipes where they look out of the stone walls, down which all the conductors are laid.

Mr. Jos. H. Williamson, who for nearly eighteen years has been the business manager of the Manufacturers' Advertising Agency, New York City, has severed his relationship with that company to connect himself with the old established Viennot Advertising Agency, No. 524 Walnut street, Philadelphia, as its business manager. Mr. Williamson will be glad to welcome his many friends at any time at his new address, either at the office in Philadelphia or at the New York office of the Viennot Agency, No. 127 Duane street, Graham building.

MANUFACTURES AND MATERIALS

SHINGLE STAINS.

70 KIRBY ST., BOSTON, MASS., OCT. 22, 1900.

EDITOR CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—We are glad to see your approving notice of the beauty and utility of stained shingle roofs, in editorial on page 186 of your October issue, but very sorry to see you giving the same approval to the hap-hazard stains that are made on the ground to suit each job. That part of the editorial tends distinctly toward the cheapening of building materials, to their injury.

We have been making shingle stains for nearly twenty years, having been the originator of this article, and as chemists who have made a study of the subject for all that time and longer, we have reason to believe ourselves more competent to speak upon it than any architect, however well equipped he may be in his own profession, or yourselves, whose ability in your profession is undoubted; because it is our profession and not yours.

For these twenty years we have tried to make an article which could not be improved upon for quality, and have guaranteed every gallon put out. We have used the most expensive and carefully selected pigments, ground them in our own mills, formulated them in our own laboratory, and compounded them in our own works; and yet the gentleman who penned the editorial in question appears to think that any painter, acting under the direction of any architect, can make a good enough shingle-stain by stirring color into a vehicle, without knowing with any accuracy what the color is, chemically, or whether the vehicle is one that will benefit the wood. Would he take the same position regarding paint, or varnish, or other materials?

We know from many analyses that these "mixed-on-the-job" stains are nine out of ten of them hap-hazard; with vehicles of kerosene or other worthless and inflammable petroleum product and pigments stirred in with a paddle without grinding. The use of these stains, by architects (and others) who do not realize that a true and good stain requires as much care and experience to make as a good paint, has given shingle-staining in general a doubtful reputation among the undiscriminating, and we dislike to see a journal of your standing giving encouragement to such things "on the ground of cheapness." Hoping that you will see the propriety of our protest, we remain

Yours truly,

SAMUEL CABOT.

[The portion of the article which referred to the use of "mixed-on-the-job" stains, was not an expression of opinion by the writer, but a statement of the opinion expressed to him by an architect.—EDITOR C. A. & B.]

MANUFACTURING NOTES.

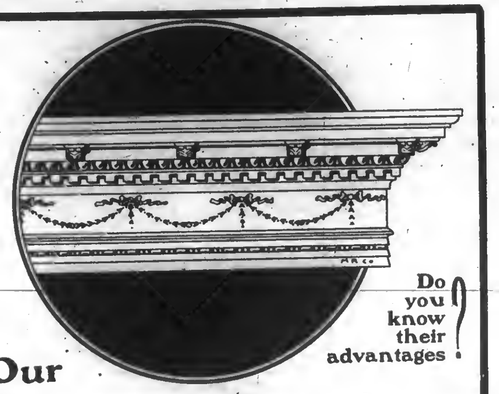
The Canadian Litholite Company, of Owen Sound, has been incorporated with a capital of $50,000.

A large deposit of clay suitable for the manufacture of paving bricks has recently been discovered at Wabigoon, Ont., and a brick manufactory will be established there.

Inducements in the form of a bonus of $2,000 and an excellent water privilege are being offered by the citizens of Tamworth to secure the removal of the cement works from Marlbank to that town.

A syndicate represented by Messrs. S. F. Mackenzie, G. H. French and J. Jeffries, has been organized to develop an extensive deposit of terra cotta and pottery clay on Salt Spring Island, near Vancouver, B.C.

Application for incoporation has been made by the Imperial Sand, Brick and Stone Company, with a capital stock of $200,000. The company controls a valuable manufacturing patent process. The head office of the company will be in Toronto. Mr. Chas. D. Warren, president of the Trader's Bank, will be president and managing director.



Do you know their advantages?

Our

Metallic Cornices.

Light in weight, easily erected, durable, handsome in effect, fire-proof, and economical.

For improving an old building, or for any class of new structure, you'll find them invaluable.

In addition to the many artistic designs shown in our Catalogue, we make them to any special architectural design required.

If you'd like an estimate, send us your specifications.

VOL. XIII.—No. 12. DECEMBER, 1900 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited,
Publishers,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to foreign subscribers is $2.50. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 15th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

ANNOUNCEMENT.

The publishers of the CANADIAN ARCHITECT AND BUILDER have decided in future to issue two editions of the journal, one to be known as the "Architects' Edition," the other as the "Builders' Edition." The former will be artistic in appearance, and the character of matter and illustrations will be specially adapted to the requirements of architects. The price of this edition will be $3.00 per year. A large number of architects throughout the Dominion, whose advice has been asked, have signified their cordial approval of this change, and their willingness to pay the increased price. It is proposed to exercise the greatest possible care in the selection of illustrations for this edition, and to use the most expensive and effective methods of reproduction. In addition to examples of the best work of Canadian architects, there will be published in each number one or more illustrations of foreign work. Thus, Canadian architects who may not be in a position to subscribe for a number of architectural publications, will be kept in touch with the efforts of the most skilled architects of the United States and Europe.

The Builders' Edition will contain matter of a practical character to meet the requirements of persons engaged in the various building trades. Much of this matter will be illustrated in a manner to clearly explain what are believed to be the best methods of carrying out various kinds of work.

It is believed that by this change the publishers will be able to meet, in a manner more satisfactory than in the past, the requirements of both classes of

readers, and that, as a result, a larger number of subscribers will be secured.

The publication of the journal in two editions will begin with the January number.

A series of valuable articles has been secured for publication next year, which includes the following: "The Best Means of Reducing the Fire Loss in Buildings," by Edmund Burke, architect, Toronto; "Landscape Architecture," by Frederick G. Todd, Landscape Architect, Westmount, Montreal; "Planning," by S.H. Townsend, architect, Toronto; "Electrical Work as Applied to Buildings," by R. A. L. Gray, Electrical Engineer, Toronto; "Architectural Education for Canadian Students of Architecture," by Professor S. H. Capper, of the Department of Architecture, McGill University, Montreal; "Design," by J. C. B. Horwood, architect, Toronto; "Decoration and Furnishing," by W. H. Elliott, Toronto.

The authors of this series of articles have been selected with a view to their special knowledge of the subjects on which they will write. The subjects have also been carefully chosen with the object of furnishing a variety of matter calculated to interest and instruct all classes of our readers.

Other valuable articles will be published throughout the year, and every effort will be made to enhance the value of the CANADIAN ARCHITECT AND BUILDER to its readers.

Students' and Draughtsmen's Competitions.

THE attention of Canadian architectural students is again directed to the Students' and Draughtmen's competitions, particulars of which are printed in the Students' Department of this issue. These competitions are organized for the purpose of developing students' and draughtmen's knowledge of drawing and design, thus fitting them for the successful practice of their profession in years to come. It is earnestly hoped that students will show their appreciation of the object of these competitions, and encourage their continuance by participating in them to a larger extent than heretofore. Architects are requested to bring the competitions to the notice of their students and draughtsmen and encourage them to enter.

Manual Training

REFERENCE has been made on more than one occasion to the opposition manifested by the Trades and Labor Council of Toronto to the introduction of manual training in the public schools. We have never been able to understand why the representatives of skilled labor should oppose a movement which is so manifestly calculated to confer benefit upon their children. It is perhaps fair to assume that in the majority of cases the ranks of mechanics are replenished by the children of mechanics. How can it be an injury to the parents of these children that their offspring should have the opportunity in the public schools to obtain a knowledge of the use of tools and the theory of mechanics? If there is any benefit whatever to be gained from educating the eye and hand of the child, surely it is the working class who will receive the larger advantage. There has been a well founded objection made that the course of education in the public schools of Canada in the past was calculated to develop clerks and professional men rather than mechanics. Now, when a well thought out plan of manual training in the schools is put in operation through the philanthropy of Mr. W. C. McDonald, we have the spectacle of the Trades and Labor Council resolving to establish a labor paper with the principal object of opposing the progress of the movement. Could anything be more shortsighted and inconsistent?

Effect of Storms on Building Construction.

THE devastation wrought at Galveston, Texas, by a cyclonic storm, affords opportunity for investigation of the character of construction best adapted to withstand extreme wind pressures. It is understood that some buildings withstood the storm. Thus the means of enquiry is at hand, and it is to be hoped that some data on this important subject will be recorded. In Canada we have had no storms approaching in velocity the one in Galveston, but of late years, as the protection afforded by the forests has gradually been diminished, our buildings have been subjected to greater wind pressures than before. Within the last month we have experienced storms in which the wind travelled at the rate of 50 miles per hour. It is proof of the substantial construction of our buildings that so few chimneys and other projecting features were dislocated. The subject of wind pressure, however, is one which should receive greater attention in the future.

Canadian Soldiers' Memorials.

REFERRING to the article and correspondence which appeared in our last issue on this subject, the objection has been made that an arch would not constitute a fitting memorial. The argument is advanced that an arch is an emblem of victory and hence is not suitable for the purpose of a memorial. This objection, which comes from a source entitling it to consideration, appears to be well taken. Probably a group of statuary would best meet the requirements. Apart from the objection which has been mentioned, a permanent arch, if executed in a creditable manner, would probably cost a larger sum than could be raised by public subscription. Owing to the absence of public squares in the heart of the city, and the arrangement of the streets at right angles to each other, if would be difficult to obtain an entirely suitable site for an arch. If the city council had purchased and fitted up as a public square the piece of land opposite the new municipal buildings, as suggested two or three years ago, this would have afforded a suitable location. We do not know whether the land is still available, but unfortunately there appears to be no disposition on the part of the city council to make the purchase. When considering the question of cost and the probable amount which could be raised for a memorial, we are reminded of the difficulties experienced by those who have in the past undertaken to raise funds for a like purpose. It is not altogether surprising that in a new country such as Canada, large subscriptions should not be forthcoming, when even a wealthy nation like the United States will not contribute largely for such an object. The failure to obtain the necessary funds for the proposed Dewey arch is a case in point. Seemingly the only means by which a really creditable memorial can be erected is by Government funds. It would be a perfectly proper thing for the Dominion Government to make an appropriation for a National memorial to be erected at Ottawa, and for the Provincial Governments to appropriate money which might be added to by public subscription for suitable memorials for the vario

Provinces. It is desirable that early action be taken in this direction.

Competition for Exhibition Buildings.

THE Toronto Industrial Exhibition Association have sent out a circular inviting architects to submit competitive designs for a new main building and several subsidiary buildings to be erected on the exhibition grounds to meet the requirements of the proposed Dominion exhibition next year. The cost of the main building is estimated at $106,000, and of the lesser buildings from $5,000 to $15,000 each. To the author of the accepted design for the main building a prize of $250 is offered, and to the authors of the accepted designs for the smaller buildings prizes of $40 and $50. Architects are required to submit plans, elevations, perspective, and a brief specification — practically a set of working drawings. The prizes are totally inadequate in view of the requirements, and would barely cover the cost of preliminary sketches. The Exhibition Association should be aware that the best architects will not enter a competition on such terms, and therefore any designs which they may receive will be the work of the less skilful designers. Had the first prize been in proportion to the other prizes, it would have amounted to $1,000, which would have been a very modest sum. If new buildings are to be erected on the exhibition grounds—and few will deny that there is need for something better than the existing ones — the aim should be to put up structures of artistic appearance and perfectly adapted to the requirements. The individual buildings should not only be well designed, but the several buildings should be so arranged and designed that when constructed they will present a harmonious and pleasing effect. This result can only be accomplished by having some skilful architect lay out the general arrangement, and control, to some extent, the character of the designs. It will be remembered that this was the method pursued when the Chicago exhibition buildings were erected, and it was entirely justified by the result. It would be wise for the Association to place the designing of the smaller buildings in the hands of the architect whose design may be accepted for the main building, or if the various buildings are to be designed by different architects, then there should be consultation between them regarding the general arrangement of the buildings and the character of the designs. Unfortunately the competition has not been framed on proper lines, and it is hopeless to look for a satisfactory outcome. Even with the meagre prizes offered, a better result might have been secured if more time had been allowed the competitors. The one satisfactory feature of the competition is the fact that as the result of representations made by the president and members of the Ontario Association of Architects, it has been decided to have the plans which may be submitted judged by experts to be appointed by that body.

The Application of Color to Architecture.

THE subject of the application of color to architecture is one which has often times been discussed. An experiment in this direction is now to be made in connection with the buildings in course of construction for the proposed Pan-American Exhibition at Buffalo, New York. These buildings, like those at the Chicago and Paris exhibitions, will be constructed of steel and covered with staff. It has been decided to color the exterior of the buildings. The work is to be done under the direction of Mr. C. Y. Turner, of New York, who is said to have worked out a color scheme which promises to give a satisfactory effect. The predominating colors will be ivory tints for the walls, with decorations in delicate shades of blue and green. All projecting features, such as domes and minarets, will be gilded. The buildings, which are strongly Spanish in design, are roofed with metal stamped to represent Spanish tiles, and painted a dull rich red. The effect of these metal roofs is all that could be desired, notwithstanding that the metal is extremely thin, and would not stand the action of the weather for a much longer time than the period over which the exhibition will extend. In order to secure the desired color effect, small models of the principal buildings have been prepared. These are placed on a platform, laid out to scale, representing the exhibition grounds. The wall spaces on these models are covered with strips of paper painted to the desired shade of color. We presume that the coloring matter will be applied, as at Chicago, by means of a spraying apparatus. The result of this experiment will be watched with interest by architects. It does not seem probable, however, that it will have any decided influence in encouraging the use of color to a greater extent than at present on buildings of a permanent character. Even in the favorable climate of Italy, color is not applied to the exterior of buildings, except in a few instances where colored mosaic is used. The application of color to a stone building, for example, would be entirely out of place, and would greatly detract from the dignity of the structure. This has even been the effect where stone of two or more shades of color has been employed in the construction of monumental buildings. In domestic architecture, however, color is being employed to a greater extent than formerly, and when judiciously used often adds to the beauty and interest of the building. Special training and care are, however, necessary on the part of the architect to secure this result.

ONTARIO ASSOCIATION OF ARCHITECTS.

Preparations for the annual meeting in January are in progress. Several interesting papers have been promised. The suggestion has been made that the meeting should be made coterminous with the Exhibition of architectural drawings by the Toronto Architectural Eighteen Club. An added inducement would thereby be offered to architects outside of Toronto to participate in the proceedings. The Association's new rooms, which by that date will be completely furnished, should also be a source of attraction to outside members. It is understood that an agreement has been reached between the association and the Toronto Architectural Eighteen Club, by which the latter organization will enter the Association as a body. This accession to its membership from the ranks of the younger men in the profession, should greatly benefit and strengthen the association.

QUESTIONS AND ANSWERS.

Would you kindly give us a price per yard for blasting and taking out of ordinary granite rock out of pit say 12 feet deep and 12 feet wide, also price for surface blasting.

Answer—We estimate that the cost of blasting and taking out granite rock from a pit 12 feet deep and 12 feet wide would run from $3.50 to $4 per yard, and the price for surface blasting from $2.75 to $3 per yard, according to the nature of the material.

A BRIEF HISTORY OF THE SCHOOL OF PRACTICAL SCIENCE.

THE banquet to be tendered on the 21st inst. to Professor Galbraith, principal of the School of Practical Science, Toronto, by the faculty, graduates, and undergraduates, has naturally carried the thoughts of many back to the early days of the school, as almost since its inception the name of Professor Galbraith has been regarded as synonymous with the success of the school. Established in a modest way to meet the demands for technical and scientific education, the growth of the institution has been almost phenomenal, until the increased accommodation provided from time to time is now entirely inadequate.

The present School of Practical Science is the successor of the College of Technology, an institution which was practically an evening technical school for artisans and others, and which occupied the building of the present public library, at Church and Adelaide streets. The origin of the present school dates from January 30, 1877, when the Legislative Assembly, in accordance with the recommendations of a report to the Hon. Adam Crooks, Minister of Education, by Professor James Loudon, sanctioned the proposal for the permanent establishment of a School of Science, and authorized the erection of a new building upon a site in proximity to the University of Toronto. The character of the institution was greatly changed, and under the new arrangement the chief object of the school became the teaching of engineering and applied chemistry. It was decided by an arrangement with the Council of University College, to utilize the teaching power of that college which already existed for the like objects in four departments and could be made applicable to the wants of the School of Science, and in addition thereto to appoint a professor of engineering and such assistants as might be found necessary. This arrangement continued until the end of 1879, when the departments of science were transferred from University College to the University of Toronto, under the operation of the University Federation Act. That the students might continue to receive instruction in the above departments in the same manner, the School of Science was affiliated with the University of Toronto.

PROF. GALBRAITH,
Principal School of Practical Science, Toronto.

The building erected at that time forms the north wing of the present school. Besides being the home of the engineering classes, it furnished accommodation for the departments of biology, chemistry, and mineralogy of the University, the engineering department having but one floor.

The first calendar of the School of Practical Science is denoted as the session of 1878-79, and the faculty consisted of H. H. Croft, D.C.L., professor of chemistry; E. J. Chapman, Ph.D., L.L.D., professor of mineralogy and geology; James Loudon, M.A., professor of mathematics and natural philosophy; R. Ramsay Wright, M.A., B.Sc., professor of biology; J. Galbraith, M.A., Assoc. Inst. C.E., professor of engineering; W. H. Ellis, M.A., M.B., assistant professor of chemistry. The attendance at the school in this year was six students.

From the calendar we notice that there were three courses, namely: (1) engineering; (2) assaying and mining geology; (3) analytical and applied chemistay. Regarding the engineering course, it is stated that in the absence of a machine shop visits to workshops and excursions during the long vacation will be taken advantage of.

An important event in the history of the school occurred on November 6th, 1889, when Professor Galbraith was appointed principal and the management of the school entrusted to a council composed of the principal as chairman and the professors, lecturers, and demonstrators appointed on the teaching faculty of the school. Recognizing the necessity of embracing every branch of applied science, the principal decided to extend the curriculum of the school so as to embrace five regular departments of instruction, in each of which diplomas would be granted, namely, (1) civil engineering (including mining engineering); (2) mechanical engineering (including electrical engineering); (3) architecture; (4) analytical and applied chemistry; (5) assaying and mining geology.

In 1889-90 the management of the school was entrusted to a council of five, consisting of Professors Galbraith and Ellis, and Messrs. C. H. C. Wright, B.A. Sc., lecturer in architecture; T. R. Rosebrugh, M.A., demonstrator in engineering; and L. D. Stewart, O.L.S., D.T.S., lecturer in surveying, with Professor Galbraith as principal. These five are still members of the council, which has been enlarged to include A. P. Coleman, M.A., P.L.D., professor of assaying and metallurgy; J.A. Duff, B.A., lecturer in applied mechanics; G. R. Mickle, B.A., lecturer in mining, R. W. Angus, B.A.Sc., lecturer in mechanical engineering; A. T. Laing, B.A.Sc., demonstrator in surveying; and J. W. Bain, B.A.Sc., demonstrator in analytical chemistry. In addition six Fellows have been appointed from among the late graduates.

As early as 1888 the necessity of providing increased accommodation was recognized by the Government, and an appropriation made for the erection of a large addition to the building. This addition was completed in 1891, the equipment and the laboratory plant installed being of the best then procurable. The building as now occupied represents a floor space of nearly 60,000 square feet, but, notwithstanding, the accommodation is overtaxed, and the work of the teachers made laborious by the necessity of repeating lectures and laboratory experiments three or four times in order that all students may receive the instruction. It has also been found necessary, from the same cause, to abandon certain experimental and research work.

That the School of Practical Science is meeting the demands of the people is clearly demonstrated by the almost constant growth in attendance. The present year is the largest yet on record, the attendance being about 220.

It is interesting to learn that the graduates of the School of Practical Science are finding employment in connection with the development of the natural resources of the country, and that many of them are now occupying responsible positions. A glance at the calendar shows that of the 263 living graduates of the school, about 75 per cent. are employed in Canada, while the remaining 25 per cent. are scattered over other parts of the world.

PROFESSOR GALBRAITH.

The head of this admirable institution, Professor John Galbraith, is a son of the late Thomas Galbraith, of Port Hope, well known to every Scotchman in Canada as the Canadian agent of the "Scottish American." He was born in Montreal on September 5th, 1846, and educated at the Port Hope Grammar School and Toronto University. At the latter he took several scholarships in mathematics and general proficiency, and graduated in 1868 with the degree of B.A., securing the gold medal in mathematics and the Prince of Wales' prize for general proficiency. In 1875 he was granted the degree of M.A. He studied engineering under Mr. George A. Stewart, chief engineer of the Midland Railway, and was admitted as a Provincial Land Surveyor. He was employed for some ten years in railway construction work on the Intercolonial Railway, the Midland Railway, location of the Georgian Bay branch road, and exploratory surveys for the C.P.R. He was also employed for some time in the Portland Co.'s locomotive shops at Portland, Maine, U.S., and did consulting work in hydraulic engineering, receiving the appointment to the chair of engineering in the School of Science in the fall of 1878.

Professor Galbraith was one of the founders of the Canadian Society of Civil Engineers, serving for five years on the council of that body. He is also an associate member of the Institute of Civil Engineers of London, England.

As Principal of the School of Science, Professor Galbraith has labored zealously, and to him is due much of the credit for the high degree of efficiency which has been attained. At the outset he had an object in view. This was to fit the student for active professional work by giving him a thorough training in scientific principles rather than by attempting to give him a so-called practical training. It is along this line that the efforts of the school have been concentrated, and the wisdom of such a policy seems to be borne out by the results. If one were to enquire from any of the co-workers as to the secret of Professor Galbraith's success, the reply would probably be that it was due to his great qualifications in the direction of organizing the work at the school. As remarked by an intimate acquaintance, "he is a wonderful organizer."

After having completed his 21st year as head of the school, the proposed banquet to be tendered him is a fitting tribute of respect.

Geo. Bathy, of Wallace, N. S., is erecting a large brick factory in conjunction with his quarries. Formerly quite a depth of clay has had to be removed in order to reach the stone and this has been a serious drawback. The removal of this clay, which is fine material for brick manufacture, will result in stripping stone.

SOURCES OF ORNAMENTATION.

By FRED T. HODGSON, MEMBER O. A. A.

BEFORE proceeding with this essay, it may not be out of place to ask of ourselves, what is meant by ornament? Ornament, I should say is any design which may be added to any object with a view of making that object more beautiful or more interesting, but which would not be of special interest by itself. Ornament, then, is something introduced to give interest to an object other than it would possess without it. It is very important then, to bear in mind that the interest of ornament is, on this account, relative, and not absolute, because upon that consideration depends the truth of the views we may take regarding the proper adaptation of ornament. If we looked through the various classes of ornament, we should find that there were two divisions into which they are merged in regard to their application—that is, they were employed either to diversify or give interest to a surface otherwise uninteresting, or that they were applied to emphasize some part of the object ornamented—and especially to emphasize function and to draw attention to the most important part or parts of the object. The first named class might be distinguished as "surface ornament," the latter as "functional ornament," or ornaments raised above the surface, or in relief.

The poet Keats has beautifully told us, that "a thing of beauty is a joy forever," a trueism every intelligent being will accept without argument, but, we are compelled at this point, to propound another query, and ask "What is beauty?" A confessed difficulty lies at the very threshold of such an inquiry. We are at once confronted by an appeal to individual taste. A Chinese or even a Japanese will acknowledge no overpowering emotion in the presence of the noblest relics of Grecian antiquity—the Venus of Melos, the Cupid of the Vatican, or the Psyche of the Museo Barbonico. But he will rave about "golden lillies," or a mutilated doll, with slanting eyes and a pimple instead of a nose. Therefore, we may be told, the emotion, amounting in some instances almost to physical pain, that stirs the cultured individual on a sudden glance at the grandest relics of the Phidian age, is conventional. It is only the product of his education. The Venus of Milo is a bit of marble; and a huge bronze Kylin—an embodiment of all that man can pile together of the terrible—might stir the same emotion in us, if we had been differently trained from infancy. In arguments such as these there is enough of truth to constitute a respectable fallacy. In all phenomena that affect mankind we have to consider the external as well as the internal action. The objective, if it have any independent existence, cannot be conceived independently by the human mind. Subjective and objective are as inseparable as convex and concave or vice and virtue; the one is necessary to the other. If we speak of any phenomenal action, we have to imply the mode in which that action affects the human organization. Light is to us nothing but an abstract and most puzzling term, apart from our daily optical experience. Music is divine language to the person blessed with a musical ear; while it is an unknown tongue, or simply a noise, to a very large proportion of mankind which is destitute of that native faculty. And therefore, with regard to beauty, which we may regard as the visible expression of the highest excellence, any appreciation of its lustre must depend on the

---

An essay read before the Fortnightly Club, Collingwood, Ont., Nov. 21st, 1900.

mind in which the emotion is raised almost as much as in the object which raises the emotion. Beauty, then, is something that can not well be formulated, so as to meet the ideals of all people, though we may in a measure set up a standard—an elastic one—that will appeal to the emotions of an Aryan people, but, even then, we shall find tribes and local lines which mark a certain demarcation of taste. No doubt, on the other hand, there are principles which are of more universal application. The negro represents the devil as white; but, the negroes as a rule, admire the white man rather than the black or the dusky; even as the latter admires the white woman rather than the black. Homer clothed his immortals in robes of light, goodness and purity, and thus gave to them a beauty that reached beyond the confines of human imagination, or even of human worship, and so it is that the aspiring artist must ever hunger after a beauty that no chisel and no pencil can represent.

Nature is to be considered merely the germ of ornamental art; art must develop nature's suggestions, combine her forms and, besides pleasing the eye, subserve a purpose. Forms and colors seem in nature to excite admiration of a different kind from that involved by the productions of artists. The latter must please the eye, gratify the taste, and exhibit fitness for its special intention. The art of the past, that aggregation of experience derived from the application of the suggestive hints of nature is simply a means of study to the ornamentists, an aid to the mastery of principles and rules. The range and variety of illustrations to be found in nature represent every principle on which beauty depends; its study supplies a fertility of resource, even as regards construction, as well as the harmonious arrangement of parts, the ornamentation of those parts, and as to the degree of prominence which decoration should assume. But it is in decoration setting forth the special qualities of the artistic mind, confirming what is material to a designed purpose, expressing the perception and feeling of beauty and truth in the designer, that its great interest lies.

In designing the decorator has to take into account two kinds of expression, the one definite and certain, the other conventional and capricious, the former dependent on natural principles, the latter upon association. The force of association was illustrated when in France, archaic severity in ornament, at a period when republicanism had triumphed, was regarded as "the thing," and decorations assumed a funereal aspect. In projecting ornamental designs, as in realizing this effect, mental impressions have to be taken into account in artistic rendering. Thus, in form, angular expresses strength and durability; the curvilinear, softness, delicacy and fragility.

Definite forms may be classed as the rectilinear and rectangular, the rectilinear, but oblique angled, curvilinear forms without contrary flexures, curvilinear forms with geometrical contrary flexure, and curvilinear forms with contrary natural flexure. The discovery of the means by which the expression is given to them involves an extensive process of comparison. Often their conjunction and admixture have merely the significance that attaches to playfulness and delicacy.

The adoption of ornamental treatment suitable to a material has a decisive influence on design, as in gold in sheets—beaten, raised in lobes, fluted to give strength and shadow; in wire—as in coiled, spiral, and numberless curved forms. Stone has its natural expression in masses, chambers, etc. This condition does not exclude one material taking designs proper to another. Foliage should perform no office other than ornamental, such as adding richness and variety, filling out forms and covering junctions, as in metal work. Hence the impropriety of using floral designs for brackets or bosses that are supposed to require strength and stability.

The Persians, in seeking to produce masses of brilliant and variegated color without offensive gaudiness, betook themselves to mosaics for the adornment of their walls and the exterior of their mosques, showing magnificent incrustations glistening in vitreous glaze. The radiant hues being natural, the colors and tints of real stone could not offend the sight; there was a certain sobriety even in the splendor of surface. Beautifully veined and naturally tinted woods have a charm independent of the design into which they enter, whilst the design, taking them into account, is also enhanced in its effects.

The character of material used for decorative purposes necessarily affects the essential features of the ornament. Lustrous, or dead surfaces, hues, or intrinsic qualities, are themselves constantly suggestive of new devices and effects. Mechanical operations and chemistry, brought to the preparation of materials, wondertully augment the resources of the ornamentist. Both the art and science are illustrated in enamels, which, having for their base hard, resistive substances that are ground to an impalpable powder, and blended with cohesive elements, are rendered plastic and absorptive of color, finally being fired, so placing an essentially perishable colored design beyond the reach of change.

There are mysterious properties in colors that serve the purpose of the ornamentist, and suggest various departures in design that result in excellent effects without apparent rule. The eye, for instance, possesses the power to supply the complementary color of the hue on which it rests.

A celebrated French painter remarked that "every bed of violets was surrounded with a halo of purple." Again, whatever the laws that regulate color—and theories and deductions on this point differ—their aesthetic value or influence on the sentiments must be taken into account for satisfactory treatment.

A reed, a flower, a broken stem, what significance may not attach to them when elevated to decoration? as the reed in the flutings of Corinthian columns, the flower in moulded form or beaten metal as a symbol or emblem, like the lotus of Egypt, the broken stem setting off curvilinear lines in capital or in the mouldings of a cornice, a band or frieze on a vase, or on a panel in simulated carelessness of rendering?

To what are we to ascribe the simply perfect use of color by the Orientals? Whether they use the brightest or most subdued tones, it makes no difference, the patterns are harmonious and gratifying. They value the color only as it assists the purpose of design. As all pleasing effects obtained in decorative art are referable to the conjoined or separate expression of the laws of harmony and contrast, it would seem as though by some latent principle of mind, or passive reception of the subtle teachings of nature, they had unconsciously acquired their marvelous aptitude to treat color, not only appropriately, but so as to secure the best results. It is the same with their pottery, their enamels, their silk stuffs, and their tapestry and embroideries, executed with surprising manual rapidity,

and often without a formal pattern, and not merely in color. Whether by instinct or tradition they have marvelous appreciation of true form and proportion.

A man aided by a child constructs a gigantic jar as we build a house with no other instrument than the hands and a spatula; an amphora of extreme height, and presenting beautiful corners, is produced. On the borders of the Nile females with their children make alkarazas so eloquent in form as not to need the aid of color to command admiration. With orientals the sense of the beautiful shows itself in all things.

Flat ornament is the most natural and obvious means of decorating solid surfaces, and this in conventional form. The source of this appropriateness is to be found to reside, so to speak, in the moulding or carvings of natural forms as something simply imitative, and, therefore, with all the labor and ingenuity exercised of no high order of art, and therefore not conforming to an imposing position.

In many branches of art the designs are drawn direct from nature. The designers of textile fabrics may be seen with a group of flowers freshly gathered from a garden in small vases before them arranged so as to present some novel or pleasing effects which are transferred in modified form to their patterns. The same colors or precisely the same forms may not be reproduced, but the flowers and the portion of the group dealt with are artistically wrought out.

Sometimes the flowers that serve as models for decorative metal work are pressed between boards so as to present an aspect to some extent conventionalized for treatment in his bas relief. This method of securing the original of patterns has for ages been adopted in the east, and serves to account for some of the really exquisite transformations that we witness.

Many forms of the ornamental class are not naturally supplied. Such is the Greek fret series of squares, one within another, interior lines being brought up at intervals, thus getting rid of the mere square. Arabic decoration, though very ornamental at first sight, was in reality based on extremely simple combinations. Celtic art with its mystic interwoven strap-work and grotesque monsters is chiefly formed of the higher geometrical curves and right lines, and is perhaps, the most difficult to analyze. Natural forms unless distorted, are seldom introduced in Celtic art.

It is a curious fact, that some of the choicest patterns of apparently eastern origin, of the eastern carpets, have been reproduced from the paintings of old Flemish masters—Van Eyck—Memling, and others, and the Florentine artists, such as Shirlandage and Montegna. So also with hangings, table covers and other similar products. Some of these painters simply give divisions of color and main outline of the patterns, and in place of angles substitute curves; others, like Holbein, delineate even the very stitches.

In a design of varied character the desirability of introducing a few points of resemblance between the forms, thus establishing certain affinities, provides a contribution to decoration. The securing appropriateness in the ornamentation is another requirement that has its influence in fashioning ornament. The ox heads and festooned garlands carved on the friezes of Roman temples had a practical value as betokening sacrifice, whilst in other public buildings they would have been stupid and vulgar.

Consonance of agreement with the general design is a prime element of good ornament, and it is just because this consonance is not found in ornamentation of a different purpose that the ornamentist finds so much in bygone art that cannot be utilized. The introduction of an opposing tone in colors to impart unity of effect, is a leading element in color design. The upholsterer who brings together two colors—say yellow curtains with green covered chairs—will wisely repeat the green in the curtain in a narrow strip, to harmonize with the chairs. Contrast usually involving alternation, some of the most beautiful effects of form are obtained through their connection. To the contrast of form and color decoration owes some of its happiest inspirations. A further source of beauty in ornament is derived from the prevalence of one quality in color, or of a given size of form over another.

It is noticeable that all that is lovely in landscape is produced by contrast of tone, not color—by the bright green of young shoots against the dark, sombre green of the older wood; by the gay birch with its bright leaves against the dark green pine, cedar or hemlock, and these against the deep blue sky as a background. The present advance of decorative art is largely due to more attention being paid to contrasts, and to their more skilful manipulation.

The circumstance that the mind never draws the line too close between use and ornament, has led to articles of vertu in the precious metals to the blending of both in structural forms, and with little conventionalism as regards ornament. An instance occurs to me in a silver standard consisting of a stalk with the leaves of a honeysuckle gently folded around the stalk at irregular intervals, and a flower here and there showing itself between the leaves. The richness of the material justified the labor and ingenuity expended upon it. Similarly, on vases of precious metals, nature, leaves, foliage, flowers and stems may be imitated as closely as one pleases in relief, or as undercut work, if only care be taken that it shall fill up a defined and bordered space.

In the Arabesque style of foliage and tracery there is a mild freedom which pleases the fancy, partly because no actual natural forms are portrayed, whilst yet they are suggested in the flowing outlines, in the lightness with which the ground is touched, and yet transformed in effect and the way in which the sight is lured to traverse over the whole surface. But as a means of decoration, Arabesque is to be used charily; it has indeed the charm of repetition, but where uniformity is equal the beauty of forms is in proportion to their variety. The harmony established is by analogy of size, color and form, but affinities may be carried too far. The true law of harmony is conformation and divergence.

The collected experience of artisans of the past constitutes a leading source of ornament. Carvings and mosiacs, figured tissues, stained glass, metal work, even paintings and architectural treatment of decoration supply a fund of artistic instruction, not for reproduction, but suggestive of new combinations.

The course of ornament, renewing at intervals of time features of previous periods, with new characteristics super-added, has its counterpart in seeds transplanted to new soils and climes, the change resulting in new developments that in some respects are wholly new. Thus, the growth of new features in the art of ornamentation is continuous and everlasting. One new design suggests another, and the chain lengthens and broadens as time advances, each race of mankind following that style of ornamentation that seems most suited to the peculiar qualities of its mental structure; indeed, it has been hinted that a man's liking for this or that style of ornament may be taken as an evidence that he descended from the Aryan, Semitic, Turanian or Celtic stock, according to the style he admires most.

STUDENTS' DEPARTMENT.

C. A. & B. STUDENTS' COMPETITIONS.

The publishers of the CANADIAN ARCHITECT AND BUILDER invite architectural students and draughtsmen resident in Canada to submit drawings in the following competitions:

STUDENTS' COMPETITION FOR A PORCH.

A plan, section and perspective sketch are required.

Explanatory detail sketches of certain portions may also be included.

The subject is an entrance porch to a city house of 35 feet frontage facing south or east on a 50 ft. lot. The porch to be large enough for use as a verandah, and yet not to cover all the front windows, as it is desirable to have the sunshine enter the parlor by at least one window.

The porch may be of wood, brick or stone or combinations thereof and may have flat or sloping roof.

STUDENTS' COMPETITION FOR ENTRANCE DOOR, VESTIBULE AND VESTIBULE DOOR.

A plan, and section are required and elevations of both doors.

Explanatory detail sketches of certain portions may also be included.

The subject is the entrance from the above mentioned porch. Light may be obtained for the vestibule from a window on one of the walls not occupied by the doors, or from the entrance door or wall in which the door is placed.

The vestibule must be large enough to accommodate a fair sized hat rack and an umbrella stand.

Drawings must be made with pen and perfectly black ink on white drawing paper or cardboard. No brush or color work will be allowed. Drawings should be so arranged as to admit of photographic reproduction in the illustration pages of the CANADIAN ARCHITECT AND BUILDER. The size of each page is 7x10 inches. No set of drawings must occupy more than two pages.

Competitors must send in their drawings, prepaid, under motto marked "Students' Competition," and addressed to "the publishers of the CANADIAN ARCHITECT AND BUILDER, Confederation Life Building, Toronto," prior to 5 o'clock p.m. of the dates set for the competition, viz; 1st competition, Thursday, 27th December, 1900; 2nd competition, Monday, January 28th, 1901. Each set of drawings must be accompanied by a sealed envelope bearing on the outside the author's motto and enclosing a card giving his full name and address.

The merits of the designs which may be submitted in in these competitions will be judged by a committee of the Ontario Association of Architects, whose decision shall be final. For the benefit of competitors, the judges will be requested to give a detailed criticism of each design.

Three prizes are offered in each competition as follows: To the winner of 1st position, $10; to the winner of 2nd position, $5; and to the winner of 3rd position, one year's subscription to the CANADIAN ARCHITECT AND BUILDER.

The right is reserved to publish any or all of the drawings.

NOTE—Competitors are required strictly to observe and comply with the above instructions and conditions.

TORONTO ARCHITECTURAL EIGHTEEN CLUB COMPETITION IN RENDERING FROM PHOTOGRAPH FOR STUDENTS.

The students must render in pen and ink only and to twice the size of cut.

The subject will be accompanying cut on Eighteen Club page of chapel in St. James cemetery, Toronto.

The paper to be white and to be 15" x 22"

The drawings will be judged by the members of the Eighteen Club.

There will two prizes, one of ten dollars for the best drawing submitted by students who have served for a period not exceeding five years, and one of five dollars for the best drawing submitted by students who have served for a period not exceeding three years to date of issue of December number of CANADIAN ARCHITECT AND BUILDER.

The drawings must be signed by author's name and must be accompanied by a letter stating length of service and signed by one of the firm in whose office the pupil is serving.

The best drawings in each class will be hung in the Eighteen Club's exhibition from Jan. 26th to Feb. 9th, 1901; and the best drawing submitted will be reproduced in illustrated catalogue and both prize and honorable mention drawings will be published in the CANADIAN ARCHITECT AND BUILDER.

Every competitor will receive a copy of the Toronto Architectural Eighteen Club's illustrated catalogue free.

Drawings must be delivered to or mailed so that they will reach Chas. D. Lennox, 71 Yonge street, Toronto, not later than noon on Saturday, Jan. 5th, 1901.

TORONTO GUILD OF CIVIC ART.

At the annual meeting held last week the following officers were elected:—President, E. F. B. Johnston, Q. C.; vice-presidents, Hon. Geo. W. Allan and A. J. Somerville; treasurer, James Bain, Jun.; secretary, A. H. Campbell. The following were appointed members of the Advisory Board:—Messrs. G. A. Reid, F. S. Challener, Allan Cassels, B. McEvoy, G. N. Morang and G. A. Howell.

By request of the Minister of Education a committee was appointed by the Guild early in the year to select the paintings annually purchased by the Provincial Government for the Normal school gallery.

The Municipal Committee of the Guild submitted to the Property Committee of the City Council a comprehensive plan of mural decoration for the City Hall and asked for a preliminary appropriation of $1,000 with which to begin the work. The Property Committee approved of the plan and of the work being done under the supervision of the Guild, but on the plea of lack of funds, the granting of an appropriation was deferred.

The Guild are trying to induce the Committee which has in hand the erection of the proposed Simcoe memorial to invite sculptors to submit designs in competition.

COLLEGE RESIDENCE AT SACKVILLE, N.B.

THE accompanying plate illustrates the handsome brown stone residence recently completed in Sackville, N.B., in connection with the college there. The main building is four stories, size 217 x 50 feet, with a rear ell, 90 x 45 feet, and was designed by Messrs. Burke & Horwood, of Toronto. It replaces the residence which was burned last year.

The students' rooms are bright, airy and commodious, and present alternating systems of rooms in pairs (study and bedroom for two), with apartments for single occupancy. The large hall in the ell is a handsome room having an open truss roof with exposed timbers, and ornamented windows.

The building contains spacious and sunny dining room, well lighted reading rooms, large office and reception rooms, Y. M. C. A. rooms and rooms set apart for hospital uses.

A large reservoir in one of the towers provides protection from fire. Drainage, plumbing and ventilation appear to have received particular attention.

COLLEGE RESIDENCE AT SACKVILLE, N. B.—BURKE & HORWOOD, ARCHITECTS.

MEMBERSHIP IN THE O. A. A.

THE attention of the architects of Ontario who are not members of the Ontario Association of Architects is called to the fact that as was proposed at the last annual meeting a special arrangement was made to admit members during the year by passing the following resolution:

"Whereas the Association is endeavoring, during the current year, to establish conditions of new activity and usefulness, and certain architects are in consequence desirous of becoming members of the Association without passing the examinations prescribed for students, be it therefore resolved that: Architects who have not registered, nor passed the examinations prescribed by the Association, but who otherwise satisfy the requirements of the "Ontario Architects' Act," and who apply before December 31st, 1900, may be admitted without passing the examinations prescribed for students, if the Council after taking such steps as may be necessary to satisfy themselves of the qualifications of applicants, are agreed as to their fitness."

This resolution was published in this journal in August and some desirable men have been added to the roll of membership, and it is the desire of the Council that further applications shall be made immediately as the opportunity ceases this month. Application should be made by sending name to the registrar, W. R. Gregg, 94 King street west, Toronto, who will bring it before the Council.

SWEDISH BRICKWORK.

SWEDEN is a country of forests, and until recently, says the British Clayworker, the domestic buildings were constructed almost entirely of wood. Time after time, however, the towns have been laid waste by fire, and from the ashes there are now rising towns of brick and stucco. The bricks are usually larger than those employed in this country, measuring about 12 in. by 6 in. by 3 in., but the size varies in different districts. For exposed brickwork, header bond is generally adopted, the angles being formed with three-quarter bricks laid alternately along each return. At Upsala Cathedral, however—which, by the way, has been restored till it looks as if it were built yesterday instead of five hundred years ago—the bond is somewhat curious, and varies in different parts of the building. Most of it is a modification of the so-called Flemish bond, and consists of two stretchers followed by a header. The effect is far from displeasing. A few modern buildings in Stockholm are faced with rock-faced wall stones, shading in color from yellowish-brown to purple. The courses vary in depth and in width of bed, so as to bond with the brickwork behind.

BRITISH COLUMBIA LETTERS.

No. IV.

PROBABLY the most important event that has yet taken place in the provincial world of art is the first annual exhibition of the Arts and Crafts Association which was held in Vancouver at the Alhambra Hall on 24th, 25th and 26th of Sept. In the absence of the association's patron, His Excellency the Governor General, the exhibition was declared open to the public by the Mayor. Several hundred visitors were admitted during the period mentioned. Somewhat more than three hundred exhibits were catalogued, and of this number far too great a proportion belonged to pictorial art; architecture, design, furniture, carving and so forth were all too thinly represented, but some exceptionally good collections of photographs, several good examples of pyrography, of stained and painted glass and embroidery and some really excellent painted china invested the crafts section with considerable interest.

Dealing with the subjects in catalogue order: the first screen was devoted to the work in oils of Mrs. Marcus Lucas whose clever sketches in the impressionist school deserved much of the favorable comment made on them; a small low-toned picture of Botany Bay, N. S. W., and a delightfully hazy morning in Burrards Inlet being perhaps the best of this member's exhibits. W. M. Forrest's amazing industry is proved by a vast amount of work. We think he would do himself greater justice if he devoted his capacity for downright hard labor to a more sympathetic treatment than to such prolific production in a somewhat stereotyped manner; his technique is too hurried and there is frequently a photographic effect noticeable; the color and motion of water is happily caught in several sketches. W. Ferris, who is another great worker, contributed many pretty subjects, nearly always well chosen, but not so frequently pleasing in color, which is too dense, particularly in the forest shades. Mrs. Watertall's study of still life was in many respects excellent and we shall expect to see a marked all round improvement in this lady's work; the other exhibits in oil were mostly very amateurish, and in too many instances were merely copies of no great promise.

Of the water colors, it was generally conceded that Mr. T. W. Fripp's drawings simply stood alone, being the only work which may be said to be really representative of the genuine old school of water color painting and following the traditions of this truly English art; in some of W. Fripp's warm, broad, sunny effects, notably in a charming little sketch of Southwold, and near Streathy, on the Thames (England), one recognizes the influence of a great master who for nearly half a century was closely connected with the water color society.

Mr. Mower Martin, R.C.A., was well represented by nearly a dozen sketches and drawings, executed with much vigor; the rather hard contrasts offered by the white, snow-topped mountains and the black green timber is scarcely true to nature, for there is always a haze, a mist, an atmospheric softening, as it were, even at sunset when the contrasts are most markedly hard; that Mr. Martin does find this softening effect is proved by some of his work, deep and rich in tone and color and certainly not lacking atmosphere; a little bit of wet cloudy April sky with patches of wet soft blue breaking through is a charming piece of sky, rock and tree; and a brilliant and luminous sketch of a siwash canoe silhoutted against a western sky out of which the sun has disappeared is admirable. Mr. Ferris' screen of water colors is chiefly made up of sketches in and around Vancouver, many pretty bits of sky and water, but we would suggest that he subordinate his foregrounds far more than he does at times, and that if he stippled less and washed or stained more he would gain both in breadth and transparency. This same lack of transparency is apparent in nearly every exhibitor's work. Water color should not be applied as an opaque, and the use of body color is entirely contrary to the traditions of the art and its best traditions; if it is desired to work in opaque mediums, why not adopt oils, pastels, tempora and so forth? The greatest beauty of water color is in its transcendental transparency of effect, which is never obtained in any other medium—the use of body color with water color is to acknowledge the want of ability to work in a legitimate manner.

Among the other exhibits in this class Miss McClung's "Fruit and Flowers" and Mrs. M. Garney's work in the same direction must be accounted much superior to the rest. Why does not the first named artist turn her attention to decorative painting, to which fruit and flower subjects are so peculiarly adaptable? A portrait study of a head by Miss Marstrandt was far and away the best black and white exhibited. The color of the neck cloth too closely approaches the tan of the flesh and mars to some extent the moulding of the chin; we should have referred to this lady's sketch in oils of a Chinese servant which shows considerable decision in treatment. Miss Marstrandt's second sketch in oils, a bit of a Lulet we think, is crude in color and harsh in treatment.

A capital piece of carving (W. F. Coulfield), of a chain of Dolphins leaping through a broken and following sea is boldly carved in English oak. A table with an inlaid top (W. Campbell), shows much technical skill and is certainly a handsome piece of work rather crudely designed, the legs being quite trivial and overladen with meaningless detail, but the workmanship throughout is first rate. A good type of quaint old Somersetshire table, known as a "court table," made in cedar by W. Bowman from a detail hy the President, was almost the only other exhibit in furniture. A fire screen designed by W. J. Bloomfield and executed in wood and leather with pyrographic decoration by Mrs. Ellis is admirable; the drawing the chief's head on the leather hanging is not quite in keeping with conventional treatment of the wood frame; the drawing of the head should have been

in the crude form characteristic of the genuine Indian drawing. Miss McClung's display of pyrography included a fine cedar chest and a number of smaller trifles in which were displayed taste and ingenuity.

Messrs. Henry Bloomfield & Sons had a fine exhibit of leaded glass and painted glass in which native flora appear frequently as the decorative motif, a step quite in the right direction. Some of the work, all of which is designed and executed entirely by members of the firm, was genuine leaded glass, that is to say, it was wholly dependent upon the utilizing of the lead lines for its drawing and to stained glass for its color, in contradistinction to painted glass, which is a picture painted upon a transparent ground.

In embroidery Mrs. Balfour Ker fully maintained her reputation. We regret to hear that Mrs. Balfour Ker intends to devote herself entirely to painting in the future. We trust this intention will not be adhered to as this lady's skill in the applied art quite exceeds her success as a pictorial artist.

When it is considered that the number of architects practising in British Columbia probably is nearly half a hundred it is surprising to find but three of that number exhibiting on the walls of the association. The disregard, not to say ignorant neglect, of the art of architecture by the public is not at all surprising. If the practice of the first and highest of the arts lie with men who are themselves so little appreciative of the real position of architecture in the world of art, or so little desirous of impressing upon the public the high nature of their vocation, what can be expected from that same public but a continued attitude of indifference? In this province an architect is so seldom believed to be an artist that if one does happen to dabble, say in water color sketching in a slight and amateurish manner, folks agree that "he is quite artistic" as though it were possible for a man to be worthy of the name of architect without being an artist, and as though there were so little scope for the exercise of artistic taste and knowledge in the vast field of unlimited opportunity to be found in decorative composition alone that the quite artistic one should be compelled to turn to trifling with pictorial art to there find scope for his artistic aspirations, restrained and cramped as they must be by the narrow limits of architecture! This is, no doubt, somewhat of a digression, but, really, an Arts and Crafts Association with scarcely a sign of the architectonic foundation upon which such associations must of necessity rest is a noteworthy curiosity. Beyond a sketch of the C.P.R. station at Vancouver by W. J. S. Parr and a neat pencil drawing of an everyday "alteration and addition" by W. Eveleigh, the only architectural drawings are by the President, whose large brown ink perspective of the Provincial Home at Kamloops was illustrated some four years ago in this magazine, as was also a design for a church in New Zealand. Among others we noticed a "rejected address" in the form of a design for a public school which was probably quite beyond the understanding of the school trustees, sketches for furniture, mantels, a chancel screen, all fully illustrated by details, and strongly drawn in brown ink and sepia after the president's characteristic method.

Mrs. Taylor exhibited a collection of photographs showing artistic perception in pose; all were soft in tone yet rather lacking in detail, probably the result of incorrect focussing of the subject to obtain the pleasing "so like a black and white, you know" effect. Messrs. Wadds Bros. also had an interesting show of photographs, one of which, a little child's head, is unaffectedly pretty and noticeably true as a photograph. But the photograph par excellence of the exhibition is a Rembrandtesque head by W. Eveleigh. Here we find all the extraordinary detail and sharpness of genuine photography, coupled with excellent pose and light, and beautiful printing. Two very large bromide enlargements by Miss Edwards must have been made from a remarkable negative, there being scarcely a defect in the enlargements.

Though mention is made last of the painted china shown by various members of the association, it must be frankly admitted that it was one of the decided successes of the exhibition. Miss Cohen, of Toronto, was represented by several pieces of decorated ware, beautifully painted and rich in tone. Among the pieces by Mrs. R. B. Ellis, a charming little jewel box and a fine punch bowl deserve more than passing attention, though all of this member's work is good. Miss McClung had some excellent work on the same tables, a pair of placques being particularly nice in color. Miss Drainie also contributed an interesting collection of examples of her skill and taste. Upon the whole, the china, as stated, was really good, showing clear painting and burning, but the natural forms so well reproduced were not always as decorative in their application and composition as they should be, and the conventional form was scarcely used — Mrs. Ellis' jewel box, decorated with a form of Persian arabesque, being the noticeable successful exception. No doubt difficulties present themselves when the decorative motif is a conventional treatment of a natural form, that do not appear where the natural form is merely copied more or less faithfully, and is really only a little picture of fruit or flowers painted on china, but the triumph of success is altogether disproportionately greater when the conventional treatment is happily brought about.

The association owes a large measure of the success of this, its first annual exhibition, to the energy of its zealous young secretary, W. C. Bloomfield; indeed, all the officers have worked earnestly to place the association upon a firm footing, and the promising nature of the exhibition just recorded, should encourage them to persevere in their good work. We had almost forgotten to make mention of the school competitions, open to children of various ages, not exceeding 16. Some 60 entries were adjudicated upon, some of them showing quite a little originality and care. It is to be hoped that the trustees of the public schools will in their turn do something to encourage and to develop a little artistic feeling and knowledge among the rising generations.

The building operations of the year must be considered in another letter, but mention must be made of a competition instituted by the C.P.R. for alterations and additions to the company's hotel at Vancouver. It appears that the building is to be almost entirely rebuilt, and several of the local architects have been invited to submit plans in the competition. The instructions (sic) are embodied in a chat with the manager, and competitors are expected to make their own surveys of the existing structure, a task of no small magnitude, if it is seriously intended to utilize it (the existing structure) to any considerable extent. It seems pre-

posterous that a large corporation like the C.P.R. should be too, shall we politely say, economical, to provide a few blue prints of the plans of the hotel as it now stands. If the competition is seriously meant it should be seriously constituted, with proper instructions drawn up with the assistance of a qualified assessor, to whom the designs should be submitted for criticism and comparison. Competitions have fallen to so low an ebb that it is well nigh hopeless for any one not having a "pull" to enter with any chance of success on merits; indeed, architects submit to "conditions" under which no self respecting association of builders would consent to furnish a single tender, and the architects have only themselves to blame if the building public accepts them at their own valuation.

THE PRACTICAL EDUCATION OF THE ARCHITECT.*

By Frederick Batchelor, F.R.I.B.A.

The advantages of general education and culture are called in question only by those who are wanting in them, but their influence on professional success is not perhaps so universally or so fully appreciated as one could wish.

The advantages of a general education to an architect are intensified by two things: namely, the more technical character that is gradually being given to it, and the catholicity of an architect's profession.

Wherever civilized man is found be he "Christian, Jew, Turk, Infidel or Heretick," he loves to make his homes, institutions, palaces and temples, not only cunning in contrivance, but each in its own way a little world of his aims and aspirations, a very Walhalla of all that is precious in art past and present, and to have impressed on each, and by a master hand, those individual, tribal and national characteristics which find more lasting if less vivid expression in architecture than the other fine arts. The designer has simultaneously to contrive, adorn and to find material expression in his work for the innermost habits and needs of every kind of client. The past may perhaps be peerless in monumental art, but I venture to think that nowhere has the range of a designer's sympathy had to be more catholic and encyclopædic than in the beautiful and loving domestic work which has marked this half-century's renaissance of architecture and its allied arts and crafts. When the tendency to the introduction of hand-and-eye training into most schemes of general education since the principles of Froebel and Slojd have been abroad is considered, it will be abundantly evident that not only has the architect's need for general education and culture advanced, but that the theory of the latter has developed on lines perhaps more akin to the calling of the architect than any other, except those of the sculptor and painter.

There can be no doubt that a sound course of general education must precede any special departure, but how soon that departure is to be introduced into the home, school or university is a misleading question. It assumes that there is but one answer, whereas there are as many answers as there are characters and callings. The Association has already done much, but I propose, with your help to organize in the coming session a regular series of technical demonstrations, both at works in progress and also in the workshop. A pupil may know the four volumes of Rivington's "Building Construction" by heart, and have visited all the works on which the staff in his office are engaged, and yet be unfit to supervise, for three reasons: Firstly, that every class of work does not necessarily find a place in the practice of even a very busy architect during the pupil's quinquennium; secondly, that a set of contractors has occasionally been known to do such good work as to deprive the pupils of their legitimate experience through rejection; and, thirdly, that visits to workshops and manufactories are quite as important as those to works in progress. I propose to meet the first want by arrangements such as have already been made with various architects and, occasionally, engineers to visit works in progress under their supervision. I do not anticipate insuperable difficulty in meeting the second want, but what we have yet to provide is a systematic series of demonstrations of good and bad materials and workmanship, and the means of distinguishing and appraising them, at sight and by applied test, taken, say, in the usual order of a specification. To meet the third want I look for the co-operation of the master-craftsmen, merchants and manufacturers in the neighbourhood of Dublin.

The timber trades alone will entail several pilgrimages. I question whether the most didactic among us would care to speak ex cathedra on the article itself. The stereotyed specification founded on the relations at one time rife between qualities, uses, ports of shipment, and market forms and marks is out of date, and the dearth of the dry red deals which stocked Dublin sheds in the good old days has not only introduced a new cult—that of the American baulk—but largely increased the demand for second Quebecs; whilst departures such as Kauri, and Oregon pines, sequoia, canary, maple, and cypress are courting attention and making new demands on technical demonstration. From the timber yards we might perhaps turn to the creosting works, and fill a few pages with notes on the process, the pounds per cubic foot injected for various uses, the pressures applied, and the depths of penetration. A visit like this, where we could handle the stuff, compare a few sawn sections, and pump the showman for all we were worth, would teach us more than a dozen text-book descriptions. After such a pleasant diversion our attention should be ripe for the saw mills and the carpentry and joinery shops.

The variety of sawn scantling now imported, especially from the Baltic, renders the appreciation of market forms in the importer's yard less problematical than when it was more confined to the log and the baulk, but it is in the saw mill perhaps that we have most to learn from technical demonstration. I imagine that one of the chief advantages of technical demonstration in the joinery shops to a Science and Art "pass" man would be the dispelling of his little illusions in regard to the present use of framed floors and tongued and grooved back-linings in cased frames. What a shock to discover that the girder and the binder have been ousted by the steel section, that the insinuating steel nail makes a better edged-joint than the time-honored tongue; that the tenacious tusk-tenon, the darling of his prettily-shaded isometrical details, is practically confined to trimming; and that so great a man as Viollet-le-Duc would drive it even from that refuge. What is even more wanted, because of its comparative neglect in this branch of technical education, is a similar demonstration in the shop-fitting and cabinet-making crafts; crafts whose niceties are only worked out by the specialist who can get a fair price and escape the demoralisation of the cut-throat competition now being fostered by government departments. I would conclude the series by an examination of some of the best examples of genuine old joinery and fittings in the last-century houses of Dublin, such as still linger in Henrietta Street, Rutland Square, Sackville Street, Kildare Street, or Ely Place; and of the old furniture in the Science and Art Museum, much of which might be measured and drawn with advantage. Few technical studies are so refining in their influence upon the design of architectural joinery as that of the good old furniture of the sixteenth, seventeenth, and eighteenth centuries, and there can be little doubt that the coarseness of the Gothic revival was largely due to its neglect. Another series of demonstrations which would very materially increase our stock of practical knowledge may possibly be arranged in connection with stone-mason's work. In these yards the various building stones in common use for constructional purposes, and also those employed in decoration and in sculpture, could be exhibited, and I hope, a number of valuable hints obtained from the master-mason's ripe experience as to what quarries have produced the stones best able to resist the disintegrating effects of our Irish climate. We would expect, too, that the flaws and defects peculiar to each description of stone would be pointed out. The methods of setting out the work and the subsequent operations of sawing, dressing, carving and polishing the stones would be demonstrated. Then again we have in Dublin quite exceptional opportunities for seeing in well-equipped workshops art metal work, constructional steelwork and foundry work in all stages of production. I venture to think that if the young architect would avail himself of the opportunities now held out to him to increase his stock of practical knowledge, that knowledge would react most beneficially, not only on the morality of the master smith, but on the pocket of his clients. He would no longer create designs, presumably for wrought-iron, which could be produced only at excessive cost in that material, or else in the form of a malleable casting which might deceive both architect and client alike.

In the details of plumber's work the average architectura student or assistant is lamentably ignorant. He is probably acquainted with the first principles of sanitary plumbing; he will not, for example, leave a soil-pipe without ventilation; he will arrange for the disconnection of the house drain from the sewer, and he may even provide for a proper current of air through the drains; but when questions are put to him by the ingenious plumber concerning the laying-out of the hot-water circulating pipes or the connection of the w. c. trap with the soil-pipe, he is liable to be placed in a position not entirely compatible with the dignity of the "arkos tectone."

From plumbing work it is not a far cry, in Dublin at all events, to enter the establishments of the master painters, for in more than one instance these trades, curiously enough, are combined.

Pilgrimages of similar scope, to the haunts of all the crafts that an architect calls to his aid, in ecclesiastical, civil, or domestic work, are in contemplation.

I have tried to put before you the paramount need of general education, of improved opportunities in the technical training which is our special stock-in-trade, and of the culture which refines their use and combines them to their best ends. Without a full measure of these things ambition is heavily handicapped. I speak, of course, of ambition in its broadest sense, the ambition to deserve and fill a niche in the Temple of Fame, not the mere instinct of self-preservation and successful plunder which we share with the domestic animal or the beast of prey; the desire to swell the store of wisdom already laid up in technical achievement and record, to raise and maintain the status of our calling, to extend without fear or favour the benefits of our ripe experience, to bear with and live down the prejudices or jealousies of our clients or fellows, and to feel ourselves efficient factors in private, social and national life—citizens, in fact, of no mean city.

I have not spoken of personal gifts, but without a fair heritage of aptitude, fostered in the hope of something better than by-ends, the seed may fall on barren soil. If we cannot choose we can at least cherish them, so that when our barns and armouries are fuller than those of the less gifted or thrifty, we can draw upon ripened grain, or take down a burnished weapon from the rack.

* From inaugural address delivered before the Architectural Association of Ireland, on October 9th, 1900.

CHURCH ARCHITECTURE IN NORTHERN FRANCE.*

By Professor J. Squair.

The subject of architecture is one possessing many aspects. We may, for instance, regard buildings from a mathematical or æsthetical standpoint; or we may consider them as successful adaptions of refractory materials to the purposes of utility or beauty, or we may consider them as reflecting the ideas and tendencies which characterize the age to which they belong. The latter is the one to which we shall confine our attention at present.

The art of France in the Middle Ages is one of great richness and variety. All the forms of literature flourished: epic poetry, lyric poetry, the drama and the chronicle. Sculpture was carried to a high state of excellence. But the architecture of the period is the richest form of artistic legacy bequeathed to modern times. An attempt has been made in the nineteenth century to revive an interest in mediæval literature and many beautiful things have been brought to our notice which were overlooked by the men of the seventeenth and eighteenth centuries. Scholars and critics have republished and expounded and sometimes modernized the great epics and dramas of the Middle Ages, but it is doubtful whether any permanent vogue regarding these works will ever be re-established. Some of great patriotic value such as the Chanson de Roland, or some of the beautiful lyrics appeal strongly to men of our time and will not be forgotten, but the number of ancient poems secured from oblivion will be small. Quite otherwise is it with architecture. Here, all the samples of mediæval art which remain are regarded with the greatest favor. The contempt which was heaped upon them by men of classical tastes has been forgotten and they have become models for the architects of to-day.

Church architecture in France in the Middle Ages is represented by two great types, the Romanesque and the Gothic. Notre-Dame de Poitiers, of the end of the eleventh century, is a sample of the Romanesque style. It is an oblong building of a type developed from the Roman basilica. Its nave and transept form a cross, its arches are round, its walls are low, and the flying buttresses are absent. From the Romanesque style was developed the Gothic. The same cruciform ground-plan is at the basis of both, but the Gothic takes an enormous flight upward. The nave becomes very high, to support which the flying-buttresses so characteristic of the Gothic style are developed. The façade undergoes marked changes, the great towers become a striking feature. Beautiful details like the rose-window and the delicate arcades are invented. The pointed arch gives also opportunities for richer sculptural displays. In the Gothic church mediæval architecture reached its climax. The great cathedrals of Paris, Reims, Amiens, Chartres, etc., have never been surpassed by other buildings in point of beauty. The thirteenth century is the period of highest excellence, but the style was continued for a century or two later.

In the fifteenth and sixteenth centuries the new movements to which the name of the Renaissance is given led men to consider more closely the art of Grecian and Roman antiquity. The result in architecture was that they began to show contempt for Gothic style and to introduce features drawn from the styles of Greece and Rome. In the façade of Saint-Etienne du Mont, of the beginning of the sixteenth century, we see this mingling of the styles. There is a Romanesque tower, a Gothic rose-window with a Grecian colonnade and pediment. After the completion of St. Peter's at Rome it became the fashion for a couple of centuries or more to build churches of a domical structure, like St. Peter's. Such are the churches of the Sorbonne, the Invalides, the Panthéon of Paris and many others. The Grecian colonnade and pediment coupled with the Roman dome are the striking features of the churches throughout the period known as the Classical in literature. The very word Gothic became a synonym for barbarous. Nothing was in good taste that was not of Grecian origin. This is one of the most striking phenomena in the history of art. The men of the Renaissance did not cast aside the Gothic style and adopt the Classical because the latter was intrinsically more artistic. Indeed, it is doubtful if it was so. They really rejected the Gothic and adopted the Classical because, under the charm of the superior Classical philosophy and poetry, they rejected their own mediæval literature and, along with it, what was no part of it, their mediæval architecture.

The church of the Madeleine of the year 1807 represents a new phase of development. It is true that it was intended by Napoleon not as a Christian church but as a temple of glory, and so could be fashioned more appropriately after the model of a pagan edifice. But that is not the only reason for its being an almost exact copy of a Grecian temple. It is easy to see by comparing, for instance, Saint-Etienne du Mont (1517) with the Panthéon (1764) that originality of design was waning. The Madeleine marks the close of the eras of invention and the beginning of the era of imitation. It is a far cry from the free spirit of foventiveness which produced a façade like that of Reims to the spirit of imitation which produced the colonnade, however beautiful, of the Madeleine. The nineteenth century is the age when men are more anxious to secure historical accuracy than to invent bold, striking novelties. The field from which to choose models has been very much widened, however, since the Romantic movement of 1830. Hugo and his contemporaries turned their attention to mediæval art and rediscovered, so to speak, the Gothic cathedral. That graceful form became again an object of admiration, and architects took it as a model for modern structures. But Romanesque and Classical models are not excluded. In fact, nearly all types of buildings are copied in our time. The two great characteristics of modern architecture are variety of style and, what may seem paradoxical, lack of originality.

* Abstract of a lecture delivered on November 19th before the Modern Language Club of University College, Toronto.

CANADIAN SOLDIERS' MEMORIALS.

With regard to this subject, Mr. A. T. Taylor, F.R.I.B.A., Montreal, writes as follows:

"I am heartily in sympathy with the project of erecting permanent memorials of the Canadian contingents who did such splendid work in South Africa in all the chief centres. Such deeds should be commemorated as an incentive for ourselves and for our children. The form you suggest for Toronto, viz., a triumphal arch, is particularly suitable, as not only following the precedent of great nations of the past, but also as being always a striking architectural feature in any city. In New York the temporary "Dewey" arch is still standing and is universally felt to be a high sounding clear note in the architectural discord of that city."

THE ONTARIO ASSOCIATION OF ARCHITECTS.

The formal opening of the new rooms which have recently been fitted up to serve as the headquarters of the Association, was celebrated by a dinner held in the Assembly Room on the evening of the 11th inst. There were present about fifty members and invited guests. The chair was occupied by the President, Mr. A. F. Wickson, having on his right the Rev. Professor Clark and on his left Professor Galbraith, Principal of the School of Practical Science. The principal feature of the occasion was an interesting address on "Architecture," by Professor Clark, a synopsis of which we hope to have the privilege of publishing in a future number. The new rooms have been partially furnished and already present an attractive appearance. The furniture in the architects' rooms was specially designed by members of the Association. It is the purpose to hold monthly meetings of the Association at which papers and discussions will form the principal feature. The rooms contain the Association Library and other interesting literature, and will be open at all times to members.

It is proposed to postpone the Convention of the Ontario Association of Architects until the 29th and 30th of January, the same week as the Architectural Exhibition of the Eighteen Club.

THE BUILDER

[THIS DEPARTMENT IS DESIGNED TO FURNISH INFORMATION SUITED TO THE REQUIREMENTS OF THE BUILDING TRADES. READERS ARE INVITED TO ASSIST IN MAKING IT AS HELPFUL AS POSSIBLE BY CONTRIBUTING OF THEIR EXPERIENCE, AND BY ASKING FOR PARTICULAR INFORMATION WHICH THEY MAY AT ANY TIME REQUIRE.]

Some Hints for Mill men.

Mill men are often called upon to get out stuff of various kinds for which no provision has been made for working out with the machines at their command. With a

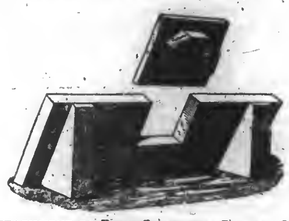

FIG. 1.—ATTACHMENT TO BAND SAWS, FOR SAWING ORNAMENTS.

band-saw, and the attachments illustrated herewith, a great variety of ornamental blocks may be produced, some of which are shown in the illustrations presented at Fig. 3. The attachment shown at Fig. 1, which is made of wood, and which any mechanic can make, has

FIG. 2.—ATTACHMENT IN OPERATION.

been used in some shops many years, and in some localities the ornaments produced by it have become quite popular for a variety of purposes. The attachment as shown at Fig. 1 may be made to cut at any

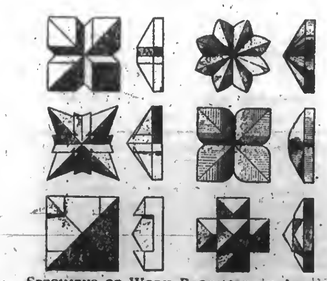

FIG. 3.—SPECIMENS OF WORK PRODUCED BY ATTACHMENT.

angle, but if made to cut at 60 degrees it will be found as useful as any perhaps. By its use hundreds of designs can be produced, the variety being limited only by the taste and skill of the operator. The few examples shown at Fig. 3 give some idea of the character of the work that can be produced, and in case an ornament or a different number of sides from 4 to 8 is desirable, the gain shown and the block may be made to suit. The manner of operating is shown at Fig. 2, when the saw is forming the cross ornament. It is necessary the block should have as many sides as the desired ornament, and that the gain be made to fit the block. It is

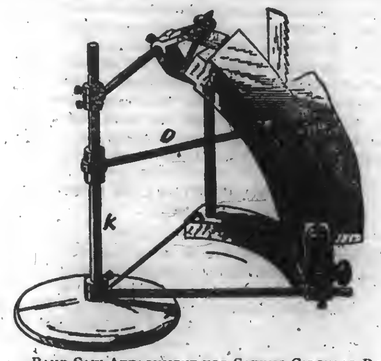

FIG. 4.—BAND SAW ATTACHMENT FOR SAWING CIRCULAR RAILS.

evident from the foregoing that many designs of center ornaments, rosettes, head-blocks, etc., that have been hitherto cut or carved by hand, may be readily and expeditiously sawn on either a scroll-saw or a band-saw. The size of the device is not material. It should, however, be proportioned to the size of the work to be done.

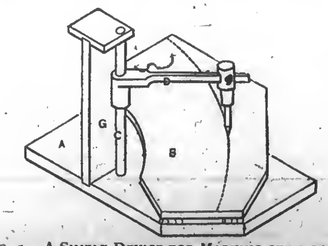

FIG. 5.—A SIMPLE DEVICE FOR MARKING OFF A RAIL.

For example, for a 3-inch rosette it would be well to make Fig. 1 about one foot long and four inches high. The gain in the inclined piece should be about 2¼ inches square and the block should fit neatly in the gain of the inclined piece. The gain and the block may be square or semi-circular. The following direction will indicate how the attachment is to be used: Cut the face figure of the ornament first, then fasten it to the block by means of wood screws as shown. Drop the

block into the gain in the inclined piece, first laying off the edges as they are to be sawn. It will be noticed in the accompanying sketches of work that the edges are all simply gauged an equal distance from the back. This, however, can be varied sometimes with good effect. The skilful operator will evolve many designs of ornament not even suggested in this brief description when he becomes accustomed to the method of working the attachment.

Cutting Circular Rail With Band-saw.

To make a hand-rail for a circular stairway has always been considered quite an achievement for the ordinary joiner to perform, though the expert finds no trouble in laying out and completing the work. The device shown at Fig. 4 was invented so that the process of forming such a rail might be simplified. This device as here presented was patented in the United States many years ago, but it seems never to have come into general use for some reason or another. The plank from which

FIG. 6.—SAWING COVES.

the rail is to be made is set up to the pitch of the stair, and the marker O which slides up and down the standard K makes the lines where the plank is to be cut for the rail. The pencil or scribe is fastened in a socket at A, the socket being moveable on the arm so as to be available at any point within the limit of the arm. The principle is an old one, in fact, as old as the works of Langley, Paine or Moxon. Another device for laying out a rail is shown at Fig. 5 which may be attached to a band-saw or to scroll saw. This machine is much simpler than the previous one. It may all be made of wood by any skilful mechanic. A shows the bace of the machine, B, an inclined board which may be hinged to the base plank. A, C, is a standard with a cap through which a rod G is fixed. The standard C carries a moveable arm D, which has a slider carrying a pencil attached. This pencil-holder slides along the arm D, in order to suit the diameter wanted. When a pattern for the rail is to be made the hinged board B is raised to the pitch of the stairs, and the pencil point is moved until the proper diameter is reached, when a line like the one dotted is drawn. The inside line is also drawn when the paper or board on which the lines are drawn, are removed and the curver transferred to the plank to be cut. The plank is then cut by the band-saw or the scroll saw, while the plank is set up on a rake which is the pitch of the stairs. By this method the proper curve and

FIG. 7.—ARRANGING SAW GAUGE.

the correct bevels are obtained; two very important items in hand-rail construction.

Some Kinks in Circular Saw Work.

THE form of outline of the slot or groove made by a circular saw not only depends on the size and the position it occupies on the saw arbor, but on the direction the material being worked is also moving. If we take a block of wood and move it across the bench lengthwise, the saw will simply cut a slot the width equal to the set, and the depth depending on the height of the table above the saw arbor. If we drive a block at right angles, or square across the saw table, a groove will be formed, having a cross section in the shape of a segment of a circle; any other direction will give a similar part of an ellipse. In Fig. 6 is shown a variety of work cut out on this principle. No. 1 is a

FIG. 8.—SAWING GROOVES AND DOVETAILS.

block cut out for lagging a pulley, or similar work; the other figures show various patterns, all of which may be cut out with a circular saw. When it is required to cut a circular groove of a given size at a saw bench, the table can be raised and the saw gauge set to the proper angle by means of the diagram shown in Fig. 7. If it is required to groove out the

block A to the line C A D, on the saw bench, using a twelve inch saw, first draw the circle E M D, twelve inches in diameter, the same as the saw, then lay off on the radius E K, E F, equal to A B, and draw a line at right angles for the surface of the table. With F for the center draw the circle T H V, equal in diameter to C D. Now the line passing through M, and touching the circle at T, will make the required angle with the line M I. From the point M, lay off at right angles to S M, M L, equal to D N; set the saw gauge at this point, with the angle already found, and the saw bench is ready for the work. The teeth of the saw, for this purpose, should be very coarse, and filed so as to cut the whole length of their sides as well as their points. If three or more of the teeth could be made shorter than the rest, and at the same time given more set, it would improve its working qualities greatly. When the saw is fastened to the arbor by means of two wedge shaped collars, the same will "wobble" or "stagger", and will cut a groove, having parallel sides, but the bottom will be concave in sections, as shown in the first diagram in Fig. 8. This can be made to give a flat bottom to the groove by jointing the saw while in motion, as shown in the second figure. By setting the saw off from the center, one corner of the groove will be made deeper than the other, but the sides will remain parallel. A dovetailed shaped groove may be made by tilting the stuff first on one side, and afterwards on the other, specimens of the dovetailed groove are shown in the lower sketches. Door stiles and door rails may be plowed for the panels by "wobbling" the saw as shown, and the panels get a better "grip' when fitting in a sawn groove. The size of the groove may readily be obtained by the proper adjustment of the bevelled washers; they can be turned on the arbor to give the saw the proper angle, and when the right position is once found, the washers and the saw can be marked, and the same adjustment can be made with little trouble when the same size of a groove is wanted. The bevel washers may be made of hardwood—maple being about as good as any—and one pair of washers may be used for several sizes of grooves. The washers, if made of wood, should fit loosely in the arbor and should be true on both face, and each should be the exact counterpart of the other. In fact, it is better, when making the washers, to make the two out of one piece of stuff, boring the hole first, and then sawing them across the hole to the proper bevel. The iron collar and outside washer must be retained on the mandrel. The first bevel washer fits against the collar, then the saw is run on, then the round wooden washer, with its thick end opposite to the thin end of the first washer, then the rim washer, which must be followed by the tightening nut. The saw will then stand at an angle with the mandrel, and this is the object attained.

The Hanover Portland Cement Company are enlarging the capacity of their works from 200 barrels to 300 barrels per day.

PROMINENT CONTRACTORS

MR. J. B. MCMANUS.

One of the best known contractors of late years in the Maritime provinces is Mr. J. B. McManus of Memramcook, N. B., who has become particularly known as a builder of sub-structures in bridge work, and who has been handling large contracts of a general character though he seldom now turns his attention to the erection of buildings.

Mr. McManus was born in Memramcook in 1846 and is a son of Terrance McManus, a native of the north of Ireland who settled in New Brunswick when about twenty years of age, and who for some years with his sons did business under the name of T. McManus & Sons.

For some twenty years previous to 1894 J. B. McManus and his brother J. W. McManus were the only members of the old firm. At that date they dissolved the partnership and each is now doing business under his own name.

Mr. McManus does a large amount of work throughout the Maritime provinces and in New Brunswick especially for the Provincial and Dominion governments.

Among the many contracts handled during the last few years might be mentioned the building of two large breakwaters in the summer of 1899, one in Kings and one in Shelburne county; also one that cost $20,000 in Guysboro county. In company with other well known builders, who formed with him the firm McManus, Lowe & McManus, he aided in the construction of the big under blast and open hearth furnaces at Sydney, C.B., for the Dominion Iron & Steel Co., the cost of which approximated $60,000.

Mr. McManus is just completing for himself a residence in Memramcook which is one of the finest in that section.

METHOD OF FINDING DIRECTION OF JOINTS IN ELLIPTICAL ARCHES.

EDITOR CANADIAN ARCHITECT AND BUILDER:

DEAR SIR,—Your diagram Fig. 1 in this month's BUILDER showing the manner of finding the direction of joints in semi elliptical arch, is not correct. The tangent as shown, or at least a line parallel with a tangent, is all right when applied to circles, but wrong in a semi ellipse. The most practical way to correctly draw those points when a semi ellipse has been drawn with a string is to draw lines from the foci to the point where the joint is required and bisect the angle thus obtained, which will be the correct joint.

JOHN HANRAHAN.

ANSWER.—Theoretically our correspondent is quite right, but his method is not in general use among bricklayers as it takes too much time to obtain the correct lines, and the method shown in Fig. 1, November issue, is often employed instead because of its quick application, and it is approximately correct. Most so-called elliptical arches are simply semi-ovals, being composed of segments of circles, and the rule given applies to such arches with correct results.

The coroner's jury at Ottawa charges the city building inspector with dereliction of duty in allowing an imperfect wall to remain standing. The falling of the wall recently caused the death of two persons.

AGENTS FOR CANADA

BUILDING MATTERS IN PRINCE EDWARD ISLAND.

[BY A TRAVELLING CORRESPONDENT]

In the last year building operations have been a good average in Prince Edward Island, though at the beginning of the year the prospects seemed very poor. A very good class of larger buildings has been erected, including a number of churches and other public buildings.

There are a few fairly important works now in process of completion, and large buildings will be proceeded with next year.

Business in most other lines has been prosperous and trade have been brisk. On the western end of the Island the construction of the new railroad, which is to extend eastward across the river from Charlottetown, involving a large expenditure for a bridge, which is over a mile in length, will mean a great outlay in money on the Island, and must surely fortell much building construction apart from the railway. Tenders for this railway work have already been clored, and spring will see construction begin.

An Engineer has for some time been engaged inspecting quarries located along the Nothumberland Straits between here and Newcastle, N.B., in the interests of M. J. Haney of Toronto, contractor for the sub-structure of the Hillsboro Railway Bridge near Charlottetown. The stone may be purchased from some quarry, a quarry may be bought out, or if a suitable location be found, a new one may be established; about 60,000 yards of stone may be required. The contractor is now getting his materials on the ground, and construction will begin as soon as navigation opens. The bridge and approaches is 4500 feet over all, having 13 piers and abutments, the 14 spans being 210 feet each. The depth varies to 60 feet, piers resting on piles or caissons. The bridge will be 25 feet above water. The substructure is to be completed in two years. Mr. Haney is of Toronto, and was one of the firm of Hugh Ryan & Co., who built the Sault St. Marie canal.

The Roman Catholic Church at Souris now under construction by contractors Duffy & McEachern, under W. C. Harris, architect, is of stone and will cost about $30,000. Souris stone is being used, which is of a reddish brown color. The walls are now raising, and the building is to be completed next October.

Few residences were erected in Charlottetown this year. All were of wood and were not expensive. Of public buildings in the city, some in particular should be noted.

The Prince of Wales College from plans by C. B. Chappell is of brick and stone from the Stevenson quarry in Wallace, N.S., with slate roof, size 132x80 with full basement and of two stories. The structure cost about $40,000.

The Prince Edward Island Hospital, recently completed under the same architect is of brick and stone, size 125x40 with a number of small ells. The main building is of three stories. There are 25 beds, public wards and 10 private rooms. The cost was $20,000.

The Brown dock built last year under C. B. Chappell is of brick with stone front. Size 80x70, 3 stories and cost $15,000.

The new Christian Church just completed by H. & S. Lowe, contractors, is of brick and stone, is not very large and cost about $5,000. It's erection was begun in the summer under W. C. Harris, architect.

An addition to the Hotel Davis, size 60x40, five stories cost $10,000. This was done last summer, C. B. Chappell, architect.

The addition of a large brick and stone wing to the Lunatic Asylum in Charlottetown is still being proceeded with, but is nearly finished. This wing is of size 200x40, three stories and basement, and is from plans by C. B. Chappell, architect. Wallace finestone was used. The cost is about $35,000.

The only large building, the erection of which is settled upon for the spring in Charlottetown seems to be the Derbrisay Co. block on Queen and Grafton streets. This is to be of stone and brick, size 40x60, and of three stories, to cost $10,000. W. C. Harris, architect; H. & S. Lowe, contractors, will start the job at once and proceed through the winter.

The new Sinclair and Stewart departmental store being constructed in Summerside by Messrs. Sherman & Lefurgy of that town, from plans and under supervision of C. B. Chappel, Architect, is taking shape as one of the finest structures on the Island. It is brick with front of brick and stone. Size 106x36, with a vault and elevator addition at the back of 10 fee depth. It is three stories in height with a large basement. The building compares most favorably with the big Holman departmental store block beside which it stands. It is to be finished early in the spring.

Messrs. Schurman, Lafurgy & Co., an old firm located in Summerside do a large business, and have a large plant in operation in that town. Recently they have taken many large contracts in Sydney, C.B., and now have quite a plant established there.

The Mechanics' Manufacturing Co., general contractors and builders, are doing a large portion of the Island trade now. The firm was organized and began business in Summerside four years ago. They have now large factory buildings, comprising a main shop of two stories, 60x50 with one ell of 25x30, and another of 35x30, in addition to large dry kilns, furnace and engine rooms, etc. The firm imports lumber, including all that they require for their own use, and now they have some $8,000 worth of stock on hand. The past season has been a busy one with them. Among other buildings erected this year by them, are:—St. John's Anglican Church in Milton, and the Indian River Roman Catholic Church, which are not yet finished. The latter is of wood, size 117x65, and will cost from $12,000 to $15,000.

C. B. Chappell, architect, of Charlottetown, made the plans and supervised the large new Halifax Herald building now being erected. His plans for the Sydney Academy in Cape Breton, made in competition, were accepted and the building was begun last August. It's size is 106x75, two stories and basement. Messrs. Schurman & Lefurgy, of Summerside, have the contract at $30,000. The building, which is of brick and stone, will probably cost about $40,000.

Mr. W. C. Harris, architect, for many years in Charlottetown, is now located at Halifax. Besides the church at Souris, he made the plans of several wooden Roman Catholic Churches now being erected on the Island.

Since its organization only eighteen months age the British Fire Prevention Committee has made sixty-three tests of materials as follows: Fire-resisting floors, twelve; ceilings, two; fire-resisting partitions, nine; different forms of wood and iron doors, twenty-three; various forms of glazing, eight. Besides this there have been several odd tests with treated wood, fire curtains, fire blinds, girder coverings and safes.

ARE YOU LOOKING FOR

Reliable Canadian Architectural Varnishes ?

IF SO

You Will be Perfectly Safe in Specifying

The Imperial Varnish & Color Co.'s Limited

HIGHEST GRADE ARCHITECTURAL VARNISHES

The several brands are carefully made to do the work designed, are perfectly matured, always uniform, reliable and guaranteed to do the work claimed for them.

Put up only in cans—never in bulk.

Manufactured only by . . .

TORONTO, ONT., CANADA

For Sale by Hardware and Paint Dealers.

QUANTITIES OF MORTAR REQUIRED FOR BRICKWORK.

VANCOUVER, Nov. 24th, 1900.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—In an article in the CANADIAN ARCHITECT AND BUILDER for October last, under the heading of "Quantities of Mortar Required for Brick per M" (page 196) it is stated that for a joint of ¼ to ⅜ in. brickwork, it will require 4 to 5 cubic feet of mortar to 1 M bricks, or say an equivalent of 2 feet 6 inches per cubic yard.

In the CONTRACT RECORD of Oct. 17th, page 4, under the heading of "Brickwork" it is stated that one cubic yard of mortar will lay 80 feet of brickwork, or three cubic yards. Now a third of a cubic yard of mortar is 9 feet, that is equivalent to 9 cubic feet of mortar to one cubic yard.

Result—Author of article in CANADIAN ARCHITECT AND BUILDER, 2 feet 6 inches of mortar to 1 yard of brick. Author of article in CONTRACT RECORD, 9 feet of mortar to 1 yard of brick.

If the editor will kindly give some accepted authority on this question it might be the means of preventing some beginner from being led astray by one of the above contradictions.

Yours very truly

THOS. BRADBURY.

[With regard to estimating the amount of mortar required to lay a cubic yard of brick-work, authorities seem to differ; this disagreement is, doubtless due to the fact that the sizes of bricks differ, some being made 8 inches long by 2 inches thick and 4 inches wide, while others are 9 x 4½ x 2½ inches. The smaller the bricks the greater number of joints, and consequently a larger amount of mortar will be required. For ordinary sized Canadian bricks, five tiers make one foot in height, therefore it requires 15 bricks to make one yard in height. This requires 15 joints, one quarter of an inch thick of mortar; in other words we have 15 horizontal joints a quarter of an inch thick and 3 x 3 feet area, in one cubic yard of brick-work. This would make a mass of mortar 3¾ inches thick, and 3 feet x 3 feet. Then we have 12 vertical joints in a cubic yard of brick-work, which also measure ¼ inch by 3 feet 3 feet each, which gives another mass of mortar 3 inches thick by 3 feet x 3 feet, less, of course, the thickness of the total horizontal joints, which will be allowed for waste etc., in this estimate. Now we have a mass of mortar as follows: 3¾ inches x 3 feet x 3 feet for horizontal joints, and 3 inches x 3 feet x 3 feet for vertical joints, or a total of 6¾ inches x 3 feet x 3 feet for the amount required to lay a solid cubic yard of brick-work. According to this estimate, which gives three joints extra for waste, etc., it requires about 4¾ cubic feet of mortar to lay one cubic yard of brickwork, but as this estimate does not make deductions for voids in slack joints, cross joints, etc., it must be evident the estimate is in excess of the requirements, though it is best when estimating to allow for the larger quantity.

Quoting an American authority on the subject (Trautwine) we get the following:

THICKNESS OF JOINTS	PROPORTION OF MORTAR	NO. OF BRICKS PER CUBIC YD.	NO. OF BRICKS PER CUBIC FT.
⅛	About 1-9	638	23.63
¼	" ¼	574	21.26
⅜	" 3-10	522	19.33
½	" ⅓	475	17.60
⅝	" 4-10	433	16.04

As these figures are based on bricks measuring only 8¼ x 4 x 2 inches the amount of mortar required to lay a cubic yard is manifestly greater than would be necessary to lay a cubic yard with Canadian bricks.

An English authority (Seddon) tells us that it requires to lay a cubic yard of brickwork "⅓ of a yard of good lime and a quarter of a yard of sand."

Professor Ira Baker in his "Treatise on Masonry Construction" says, "1 cubic yard of mortar will lay from 67 to 80 cubic feet of brickwork," and "from 90 to 108 cubic feet of brickwork with ⅜ to ¼ inch joints." This rule is also quoted in Kidder's Building Construction and Superintendence."

From the foregoing it will be seen that authorities differ somewhat, but to Canadian estimators the first figures presented in this article, namely, 4¾ cubic feet of mortar for each cubic yard of brickwork will be nearer the correct thing than either the English or American rules, that is to say, that from 0.25 to 0.30 cubic yards of mortar will be sufficient to lay one cubic yard of Canadian bricks.—THE AUTHOR OF THE ARTICLE.]

[NOTE.—The article in THE CONTRACT RECORD to which reference is made by our correspondent, was republished from the St. Louis Builder. — Editor C. A. & B.]

BUILDING MATTERS IN VANCOUVER.

The annual election of officers of the Vancouver Builders' Exchange was held recently. Only two changes were made in the personnel of the Board of Directors. Mr. W. Hepburn, succeeded Mr. C. T. Shindler as Vice-President and Mr. D. M. Fraser is replaced by Mr. R. P. Forshaw.

The Exchange cannot be said to have prospered during the year to the extent which was anticipated. In the opinion of some of the older members, a mistake was made when the annual fee was reduced to $25.

The change resulted in bringing in a member of new members, many of whom appear to have looked only for immediate personal benefits in return for their investment, forgetting the advantage which must accrue to all if by united effort trade abuses can be remedied and the business of the builder placed on a more equitable and profitable footing. The proposition has been made to raise the membership fee, and profiting by past experience it is hoped that the affairs of the Exchange may in future be managed in such a way as to ensure a larger measure of success.

The effort to induce the architects to organize and work in harmony with the Exchange failed, as did also the movement to secure the adoption of a uniform contract.

The rainy season has set in and in consequence building operations will be conducted on a smaller scale until spring.

BUILDING AT OTTAWA.

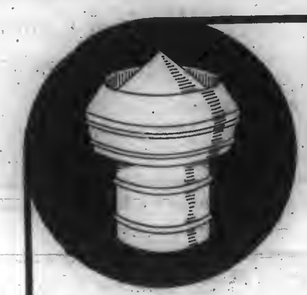
The following statistics show the character and extent of building operations in Ottawa during the building season which is about to close:

The number of solid brick or stone buildings or what may be termed first-class structures, erected during the year is 94, the estimate total cost being $391,600, of these only 10 are below $1,000, and but ten of $10,000 and over, the highest being $50,000. The great bulk, or 74 of the buildings, range from $2,000 up to $6,000 in cost.

Of second class buildings known as brick veneered structures there have been erected 187 at a total cost of $280,450. Of these 27 are placed below $1,000, and six at over $3,000, being in all cases blocks of several houses or stores, leaving 154 buildings erected at an average of $2,000 each.

The local architects state that very little work has come to them as the result of the great fire which destroyed a large portion of the city early in the year. The burned district did not include the business section of the city. The buildings destroyed were principally wooden houses of a cheap character. These have been replaced by structures of a little better description, but such as only called for the services of the local builder.

The Danish Elevator and Hoist Regulations provide, among other things, that the car must be suspended by at least two ropes or chains each of which must alone be strong enough to carry ten times the weight of the car fully loaded.



Our "Halitus"

VENTILATOR OR CHIMNEY COWL.

Made from GALVANIZED STEEL OR SHEET COPPER.

A THOROUGHLY storm-proof Ventilator, with a positive upward draft under all conditions, that exhausts more cubic feet of air per minute than any other.

It has no down draft, and can't get out of order. Made with Glass Tops to admit light, if desired.

If you want to know of a Ventilator that really ventilates, read up the "Halitus" in our Catalogue.

METALLIC ROOFING CO., LIMITED

WHOLESALE MANUFACTURERS,

TORONTO, CANADA.

PERSONAL.

I. S. Russell, architect, Stratford, Ont., who has been ill for some time is now convalescent.

Mr. Frederick F. Saunders, architect, has recently opened an office at No. 45 Lippincott Street, Toronto.

Messrs. W. A. Langton and Gregg & Gregg, architects, have recently removed to new offices at No. 94 King Street West, Toronto.

Messrs. Sproatt & Rolph, architects, Toronto, will shortly remove from the Bank of Commerce Building to more commodious offices at No. 94 King Street West.

Mr. W. T. Dalton, architect, of Vancouver, B. C., is about to leave for England, on a vacation. He proposes to spend the greater part of the winter in the old land.

Mr. W. A. Langton recently delivered lectures on various phases of architectural education and work before the students at the Normal School, Toronto, and the members of the School Art Leagues.

Mr. A. Gobeil who entered the Department of Public Works at Ottawa in the year 1872, and has for a number of years past occupied the position of Deputy Minister of Public Works, has made application for superannuation. Mr. Gobeil has been a most efficient public officer.

PUBLICATIONS.

In order to disseminate as widely as possible a better knowledge of explosives and their employment and thus reduce the risk and promote efficiency of blasting operations, the Toronto Bureau of Mines has just issued a pamphlet of 136 pages dealing with this important subject. The author is Prof. Courtenay DeKalb of the Kingston School of Mining, who is also Inspector of Mines for Eastern Ontario. The Commissioner of Crown Lands is taking steps to place a copy of this work in the hands of every mine and quarry manager, captain and foreman in Ontario, free of charge, in the hope that a perusal of its contents may lead to a diminution in the number of accidents resulting from the use of explosives. Other persons may procure a copy for the nominal charge of 25 cents on application to Thos. W. Gibson, Department of Crown Lands, Toronto.

The Amherst Red Stone Quarry Co. have turned out material for a number of large and well known buildings the last few years, including the Baptist church in Amherst erected a few years ago at a cost of $35,000; the handsome brick and stone Presbyterian church on the same street which was built last year at a cost of $23,000; the new Bank of Nova Scotia now about completed in Sussex, N. B., (this building is entirely of dressed stone and it has been found that the Amherst red stone can be worked with great ease); the Merchants' Bank of Halifax in Truro and the Roy building in Halifax contain this stone. It was used in the new Portland school house in St. John, and considerable has been sent recently to D. J. Leonys & Son, Granby, Que. The stone maiotains its color well and hardens with exposure. The quarry which is just outside of Amherst is 150 feet in length and is now 40 feet deep. It is well fitted with lifting apparatus with engines of 60 h.p. It is under the management of Jas. Donald of Amherst.

IN COMMON WITH LOYAL SUBJECTS OF THE EMPIRE THROUGHOUT THE WORLD WE DEEPLY DEPLORE THE LOSS OF THE GRACIOUS SOVEREIGN WHOSE LONG AND GLORIOUS REIGN CAME TO A CLOSE AT OSBORNE PALACE ON JANUARY 22ND, 1901. "SHE WROUGHT HER PEOPLE LASTING GOOD."

The A. I. A.

THE next convention of the American Institute of Architects will be held at Buffalo, during the Pan-American Exhibition. The choice of a meeting place seems a wise one, for outside of its own attractiveness, the city of Buffalo will have a wealth of architectural features to show in its Exhibition.

The Toronto Architectural Eighteen Club.

THE Club are to be congratulated upon the success of the exhibition of architectural drawings held under their management in Toronto last month, an extended notice of which appears in another part of this issue. Several months of earnest effort were required to perfect the arrangements for this exhibition. The expenses were met by the revenue derived from advertisements in the exhibition catalogue, the compilation and publication of which also involved much labor. The number of visitors to the exhibition was large and would no doubt have been greater but for the death of the Queen. The public lecture by Mr. Albert Kelsey, of Philadelphia, on methods of beautifying towns and cities, brought together a good audience, and was much appreciated. The exhibition has undoubtedly proved a stimulus to local architects and directed public attention to the subject of architecture—results which in themselves are important.

How to Reduce the Fire Loss.

THE recent great fire in Montreal and the consequent heavy increase in insurance rates, should not only lead to the perfecting of fire brigades and equipment, but, on the principle that prevention is better than cure, should direct public attention to the value of fire resisting materials in building construction. The Japanese Government has recognized the wisdom of such action, by giving an order to a United States manufacturer for 80,000 feet of wire glass to be used as a fire-resistant in the Imperial Japanese navy buildings at Mai Juru. The value of properly constructed division walls as a means of preventing the spread of fire within a building was well illustrated at the recent fire in the store of Marshall Field & Co., in Chicago, where by such walls the fire was confined to one section and the loss was only $25,000.

Tests of Fire Blinds.

THERE has recently come to hand a report of a test conducted last year by the British Fire Prevention Committee with fire-resisting curtains and blinds. The object of the test was to show the protection against fire afforded to a window and to a door of 20 superficial feet and 16 superficial feet area respectively, when screened from

the flames by rolling fire blinds which can be put into position in a few seconds. The test of the fire was within three feet of the face of the fire blinds, which were subjected to a temperature gradually increasing from 400° to 1600°. The blinds after 30 minutes test remained in position, the fire not having penetrated through the door or window. The test seems to show that by means of properly constructed and adjusted fire blinds the entrance of fire through windows and doors may be retarded for a time, thereby giving opportunity for the arrival of the firemen. A matter of much importance is the facilities for speedily placing the blinds in position under the most disadvantageous circumstances which could be induced by an attack of fire.

The O. A. A.

THE annual convention of the Ontario Association of Architects, held in Toronto last month, the proceedings of which are printed in this number, was one of the most interesting in the history of that organization, and likely to be productive of lasting results. It was decided to proceed at once to establish a system of instruction for students, based upon the course of study recommended in the report of the Committee on Education. The Association will memoralize the Dominion Government to throw open to competition among architects in private practice the designing of important public buildings, a system which was adopted several years ago by the United States Government, and which has worked out very satisfactorily. The adoption of the system in Canada would stimulate our architects to the exercise of their highest skill, and lead to the erection of public buildings throughout the country which would not only be carefully adapted to their requirements, but would stand as examples of refined architecture. The convention papers were of a high order of merit, and evoked interesting and instructive discussion.

MR. GRANT HELLIWELL,
President Ontario Association of Architects.

Effects of Sewer Gas Upon Health.

IT is gratifying to learn that the Medical Health Officer of Toronto is conducting an investigation to determine if possible what relation the out-flow of sewer gas from the ventilators at the street level has upon the spread of diphtheria. The noxious vapours arising from these ventilators, especially in winter when the atmosphere in the sewer is at a higher temperature than outside, have been the subject of much comment, and have been regarded by many citizens as a source of serious danger to health, and as being at least one of the causes of the prevalence of diphtheria among children. The evil is specially noticeable in the northern part of Toronto, where many of the sewers have dead ends. This section being at the highest altitude, the sewer gas from the lower districts of the city naturally rises to and finds an outlet there. The result of the investigation which is now being held will be looked for with much interest, and it is to be hoped will determine approximately at least the extent to which these ventilators are the cause of disease.

An Art Museum as a Memorial to Queen Victoria.

SINCE the death of Queen Victoria, the subject of a suitable memorial to her memory has been under discussion in Toronto. The Provincial Government has signified its intention to contribute at least $10,000 towards this object. The Premier has stated it as his opinion that the memorial sheuld take the form of an Art Museum. This opinion, we believe, will be shared by a large number of the citizens. Indeed, a movement having for its object the erection of a museum of this character was begun about a year ago by a number of public spirited citizens, and a considerable sum has already been raised by private subscription towards the carrying out of the project. It is gratifying to learn that the Government are in sympathy with the undertaking, and it is to be hoped that the proposed grant from the Legislature will be given to assist it. Queen Victoria's reign was marked by a wonderful advancement in the arts and sciences, to which advancement her liberal encouragement was at all times given. A memorial of the character referred to would therefore seem to be a particularly fitting one. Toronto has now reached a position where an institution of this kind should be established. There are few cities of equal importance, especially from an educational standpoint, in which a home of the arts does not exist. The Ontario Association of Architects, in convention assembled, passed a resolution approving of the views expressed by the Premier of Ontario with regard to this matter. Application is to be made for incorporation by an Association to be known as the "Art Museum of Toronto," and a public meeting of citizens is to be held at an early date to consider and promote its establishment. If it should be decided to give it the character of a memorial to our late Queen, public interest in behalf of the undertaking would no doubt be stimulated, and the probability of the success of the movement enhanced.

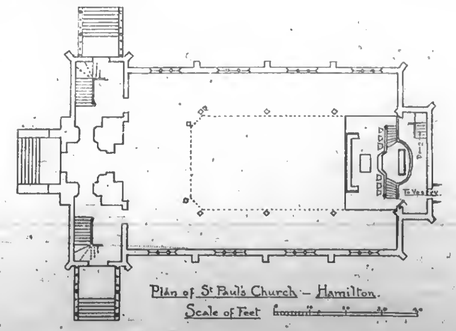
ST. PAUL'S CHURCH, HAMILTON, ONT.

The city of Hamilton possesses in St. Paul's a church which is well worth the study of architects. The present fine building is old, as the age of buildings goes in Ontario, but the parish is older still, its history reaching back to 1833 when Hamilton was a village with a population of less than a thousand. In 1833 a Presbyterian minister was first called to officiate regularly in Hamilton, and a small frame building on the site of the present church was built by his congregation and called St. Andrew's church. The founders of the parish lie in the churchyard, but they never saw the beautiful church which now protects their graves. Their headstones, inscribed in each case to the memory of a native of some county in Scotland, show that they went to their rest in the thirties and forties of the past century, whereas the present church was not built until 1857. But if the fathers of the church saw nothing of its present beauty they saw nothing also of the troubles that came upon the parish, beginning with the disruption of 1843 in Scotland which made its way to Canada in the following year. The congregation was first divided over this question, the minister leading off a portion to found a church representing the Free Church of Scotland. About ten years afterwards a second trouble began when the old church of St. Andrews was moved to another site in order to make room for a new building, which was begun in 1855 and opened for worship in 1857. Unfortunately for their peace, though fortunately for succeeding generations, the congregation overestimated their resources and undertook the erection of a more costly structure than they could finance. Though they raised the handsome sum of $30,000 there still remained a debt of about the same amount, and circumstances arose in connection with this heavy burden which led to the closing of the church for a time. Many members worshipped with neighboring congregations, while others built a brick church retaining the name of St. Andrew and the services of their minister. Thus it came about that when in 1876 there was an amalgamation of the divided congregation forming a body to resume worship in the new church it was found necessary to give up the name St. Andrew's to those who continued to worship in the brick church. and to call the new church St. Paul's. But the bell which called the new congregation together for its first service was the old bell of St. Andrew's, the oldest bell in Hamilton, which still hangs in the tower of St. Paul's church.

ENTRANCE TO ST. PAUL'S CHURCH, HAMILTON.

The building was designed by William Thomas, of Toronto. It is of course a product of the Gothic revival and one of the better class of such products, in which an essential part of the aim was honest work. The construction is genuine; the spire is of stone throughout. As is often the case economy supervened when it came to the renewable appendages of porch and steps. These were originally all built of wood, but the front steps have been recently converted to stone and the porches will no doubt follow some day. This will be a great improvement, for not only is wood too mean a material for the entrances of so fine a church, but, as there was no attempt made to imitate the proportions of stone in the wooden porches, their slender design is somewhat too light for the substantial character of the main building.

The walls are of gray Hamilton stone backed by lake shore stone, which in the interior of the spire seems piled very high for such rough material. The details are well designed and well executed. The spire is truly elegant; the pinnacles which finish the tower have the appearance so common in this type of spire of needing unification, but they accomplish the purpose of enrichment for which they were intended. The crocketted gables over the belfry windows have an admirable effect of enrichment, and the spire is a model of well balanced ornament; with a band and dormers near the bottom to combine with tower and pinnacles, and just one well placed repetition of it near the top to give the eye a resting place which divides the spire in pleasant proportions into the beginning, middle and end which every composition should have. It is interesting to observe by blotting out this upper band with the finger how uncomposed the spire is without it and how impossible it is to get the same effect of repose if the band is moved at all, either up or down.



Plan of St Paul's Church – Hamilton.
Scale of Feet

It is a pity that the traceried window under the belfry is there at all. It does not look into the church as its size and ornate character would lead one to believe, but upon a passage way into the belfry. For this a very small window would have served and it would have

been better to have taken advantage of the facts so as to keep the wall plain at this point and increase both the size and richness of the entrance below which is now too small and too plain.

The gallery stairs give an opportunity for side gables to stop the slope of the roof which has usually such an unpleasant effect in combination with a spire.

The external defect of the church is want of length in the body, but an examination of the interior shows how this came to be. It is the gallery that provides lines for the interior proportion and on the inside proportion is satisfactory. There is no doubt the church would be a finer church without the side galleries, but if these galleries were to be taken down without at the same time lengthening the church the apparent width of the church in proportion to its length would probably be greater than the eye can guess in anticipation while under the influence of the present arrangement which is carefully composed. The pulpit is the centre of attention, and is given the importance which it should have and which it is so hard to give it when it stands alone, by placing it under the arch of a spacious recess. This arch spans the whole distance between the gallery fronts, with the effect of dividing the body of the church into a central portion with wings. Even above the galleries, although the roof is a clear span, to some extent the central portion governs the eye in estimating the proportions of the church, for the gallery fronts are a strong line running to the springing of the arch over the pulpit and meeting the top of the carved screen that backs up the pulpit and forms the tying line of the arch.

The treatment of the pulpit is admirable. The actual desk upon which the preacher rests his books is but a small point in the space at the end of the church, but the full spread of the steps which extend on either side has been utilized by enclosing them with a horizontal rail to increase the width of the pulpit and its platform to the utmost. What is lacking is made up by the screen behind which spreads across the whole width of the space under the arch, a distance of nearly 30 feet. The screen might well have been higher in the centre behind the minister in which case it would have served to blot out the lower part of the window behind and prevent the minister's head appearing en silhouette to the occupants of the front seats. The window in the recess is in fact not an altogether happy feature, not only for this reason but because of the conflict of its lines with those of the arch. It is impossible to desert the springing line of the arch as a basis in designing the window. It is a difficult situation but with the help of tracery it should not be impossible to make a satisfactory combination of screen and window.

The screen is of course closed in at top and the space behind forms a passage way to the vestry and cellar.

The roof is eminently satisfactory. It has pointed trusses, purlins, rafters and ceiling boards all of dark oak. There are dormer windows on each side, an addition to the original design, which, though they are rather poor in external detail have an excellent effect inside. The light shining in between the trusses increases the vigor while relieving the gloom of the roof and the dark colour of the roof matched by that of the seating below gives a fine breadth of effect in colour.

These are the main points that attract attention in a first visit to the church, but it has an attractiveness that increases with attention and forms a wholesome example in a country where there is more temptation to over freedom than to pedantry, of the merits of scholarly work.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the Society was held in Montreal on Jan. 25th, when the following officers were elected: President, E. H. Keating, Toronto; vice-presidents, Messrs. G. H. Duggan and E. Marceau, Montreal; and C. H. Rust, Toronto; treasurer, H. Irwin, Montreal; secretary, Prof. C. H. McLeod, Montreal; librarian, W. H. Rice Roberts, Montreal; council, Messrs. J. Kennedy, Montreal; W. P. Anderson and G. H. Mountain, Ottawa; D. MacPherson, Montreal; P. S. Archibald, Moncton; H. J. Cambrie, Victoria, B.C.; W. R. Butler, Kingston; J. Galbraith, Toronto; James Ross, Montreal; H. S. Poole, Stellarton, N.S.; R. B. Rogers, Peterborough; R. Hering, New York; W. Chipman, Toronto; B. McConnell, Montreal; and C. B. Smith, Toronto.

MR. E. H. KEATING,
President Canadian Society Civil Engineers.

ILLUSTRATIONS.

RESIDENCE FOR MR. LEWIS SKAIFE AT WESTMOUNT, P. Q.—MACVICAR & HERIOT, ARCHITECTS.

The foundation walls are of limestone and the walls above base course are in red brick laid up with white mortar. The house is designed in "Old Colonial" style with woodwork of cornices, portico, and verandahs finished in white.

Entrance is obtained by wide flight of steps leading up to doric portico with columns on each side. The inner vestibule opens into a wide staircase hall with sliding doors giving access to drawingroom, diningroom and library. The broad staircase leading up to first floor will be finished in white and mahogany with oak treads and floors.

The kitchen is on ground floor with butler's pantry off dining room. A back staircase leads up to the first floor from pantry. The upper floors are arranged for bebrooms, nursery, large hall, sitting rooms, bath rooms, etc. The mantelpieces are designed in the Colonial style and the one in library is built of brick. The basement is utilized for workshop, heating apparatus laundry, etc. The heating is by hot water and the plumbing throughout is of the very latest style.

THE TORONTO ARCHITECTURAL EIGHTEEN CLUB EXHIBITION.

The exhibition of drawings belonging to the circuit of exhibitions of the Architectural League of America, which was obtained for Toronto by the association of the Toronto Architectural Eighteen Club with the League, has been an event in architectural circles in Toronto; and it is gratifying to learn that this is but the first of a series of such exhibitions.

We must however recognize that the exhibition was essentially an exhibition of drawing. It was the rendering that attracted attention principally, and was the principal field of effort on the part of the draughtsman. As such it was useful. Our own architects have not made a study of rendering as was evident from many of their exhibited works, and there is no doubt that this exhibition could give them some useful hints in the art of making attractive drawings. But it is well to enquire how far the art of making attractive drawings is helpful to the art of architecture. The real architectural drawing is of course the line drawing which marks the limit of surfaces only in order to define them for the purpose of measurement. Any other kind of drawing must be made either to help the architect to see his design in its perspective projection, or to represent to the owner the appearance of the executed work. The latter use has become a disease—a parasite that has fastened itself upon the profession, largely due to the profession's own eagerness to expose its wares. From the owner's point of view the practice is desirable, and in commercial ventures the profit in the new building often begins as soon as the design is made and a perspective can be furnished, for publication by lithography as an advertisement. The more realistic the representation and the more people going in and out of the door the better. But such drawings ought not to be called architectural drawings and there is no reason why they should be made by architects; indeed in the more lavish architectural circles they are done outside the office by specialists. The architects own work in the way of perspective and freehand drawing is done long before the design has reached the stage from which these finished drawings are made. The elevation is not the source of his studies but their product. By the time he has made up his mind enough to decide upon all points of his the elevation and completed the drawing of it his work on the drawing board is done; the rest is building.

For the purpose of this kind of tentative study the first essential is severe truthfulness. The motive of the drawing is the detection of faults; its purpose is not to show off the design but to show it up. Any kind of cooking, whether of the perspective or in the less bare-faced falsities of cloud shadows, improbable foliage, unrealizable beauty of colour, or a chic handling that is a ground of pleasure in itself is out of the question unless the designer wishes his studies to minister to self deception. On this ground Mr. Wilson Eyre, the genius of the exhibition, would be ruled out for the most part of his work. His drawings are works in themselves, and if the owner's right to the possession of drawings were to be established by the courts he would get in one of these preliminary sketches (if they are preliminary sketches) a possession for which the whole fee of one per cent. for preliminary drawings would sometimes be little enough. Mr. Eyre might, however, plead with justice that they are not architectural drawings but were made for his own gratification. They are in truth little pictorial creations founded upon his designs. Mr. Goodhue, Mr. D. A. Gregg and other skilful draughtsmen show their buildings by a drier light than Mr. Wilson Eyre does, but the excellence of the drawing too often consists in qualities of abstraction, colour and technique which would prove dangerous in a drawing intended for the scientific observation of a design by the designer. They are not therefore architectural drawings of the best type in spite of their excellences. A better model was the bird's eye view of the Pan-American exhibition sent by Messrs. Carriere and Hastings. This drawing had qualities of delicacy and clear modelling that gave it rank among the beauties of the exhibition, but its motive was a clear statement of the facts. This, the only motive that is reasonable in a purely architectural drawing, is not inconsistent with beauty, and as far as technical pleasure goes, to those who know the skill and knowledge required for its perfection, there is quite as much technical pleasure to be derived from its precise beauty as from the pictorial and decorative effects which a freer style accepts from accidents of material.

It may seem impertinent to speak of architectural drawing as a thing outside of the Beaux Arts rendering which is architectural rendering par excellence in the sense that the style is evolved from the theme and is exactly suitable for its expression. But herein lies its unsuitability for other themes, and all architecture has not the ideal conditions of that which is commissioned in the Beaux Arts schools and studios for a more splendid civilization in a better land than ours. That land of white marble colonnades with a backing of soft blue foliage is a land to dream of and to hope to go to when we die; but here, alas, white marble is not, and the trees are only green.

Yet it is from such a training as the students of the the University of Pennsylvania are receiving, who in this exhibition play like young Raphaels with the classic forms and make such beautiful drawings of their designs, that the best results may be expected not so soon however as would appear from the truly astounding skill they seem to display. Art is long. The law knows no change and respects no system, for art is not that which is planted in the mind but that which grows in it by the slow process of individual growth. But the result is all the greater for the enlargement of the mind in which the process of incubation is going on, and one great source of enlargement is facility in drawing. To have the drawing eye is to have the seeing eye which both consciously and unconsciously feeds the mind continually. If the interest in drawing which this exhibition has created does not die away without stimulating some of our younger architects to practice with the pencil and brush it will have done good service in Toronto.

Mr. Frederick G. Todd, landscape architect, of Montreal, whose office was in the Board of Trade building, lost a valuable collection of plans, books, etc., by the fire which destroyed that building last month. Mr. Todd has opened an office in the Bell Telephone building.

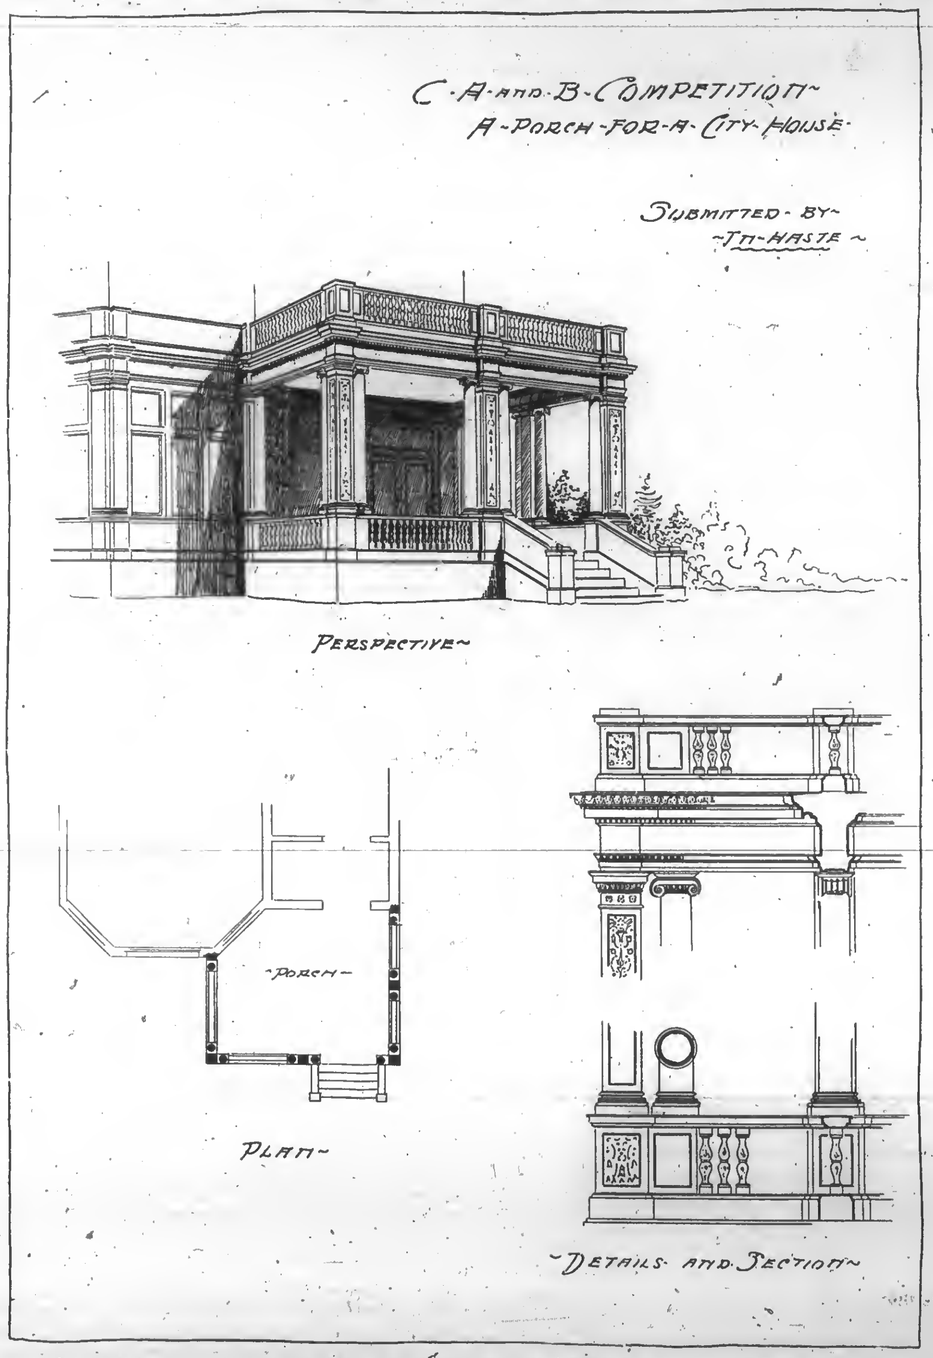
A book on "Bricklaying" by Owen B. McGinnis, of 810 West 128th street, New York, has just been published. It has been compiled from a series of articles on the subject contributed by the author to the professional and trade journals. The price of the book is not stated.

Mr. W. B. Hamilton, who for the past twenty-five years has been connected with the St. Lawrence Foundry (now the Canada Foundry), of Toronto, has severed his connection therewith, and has been appointed Western representative for Messrs. Drummond McCall Company, of Montreal. He is now located at 93 York street, Toronto.

STUDENTS' DEPARTMENT.

CANADIAN ARCHITECT AND BUILDER STUDENTS' COMPETITIONS.

The committee appointed, by the Ontario Association of Architects to judge the merits of the designs submitted in these competitions have reported as follows:—



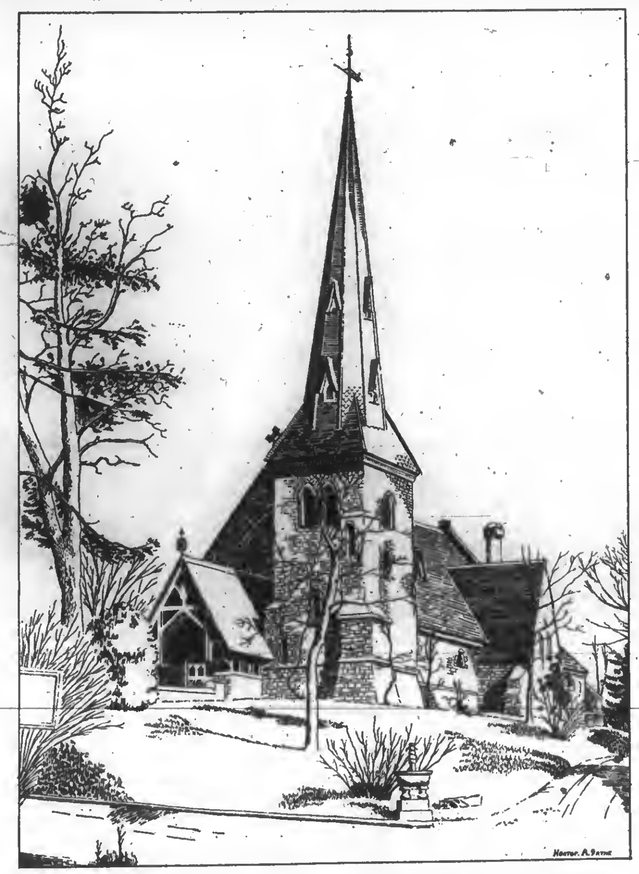
CANADIAN ARCHITECT AND BUILDER STUDENTS' COMPETITION FOR A PORCH FOR A CITY HOUSE—DESIGN BY "IN HASTE" (MR. WILLMOTT GAGNON, MONTREAL), AWARDED FIRST PLACE.

COMPETITION FOR VESTIBULE

"Victor" is placed first. This is a very commendable design in Italian Renaissance. The disposition of the somewhat luxurious features of its design, the plan, heights of doors, impost mouldings, etc., are correctly worked out in their relation to each other. We think the author is to be commended for having taken good advantage of the fact that there was no limit of cost, of having placed the problem on a high plane necessitating research and study, with corresponding benefit to himself. The rendering is clear, and displays good draughtsmanship throughout.

"Torch and Wreath" is placed second. This is a satisfactory, though not strikingly original "Old Colonial" doorway and vestibule. Its various details are of good type, though the lead work of fanlight of outer door is hardly in the spirit of the style. More light should certainly be provided in this vestibule, and this might be done by placing a window in one of the side walls. The rendering is good but a little shaky and uncertain in places.

"Drawing Pen".—We place the design marked by a drawing pen third, but must say, we had difficulty in deciding between it and "Jack," they being about equal in design and rendering, and having the same faults, a little too much elaboration, over panelling, etc. "Drawing Pen's" front door we consider better than "Jack's," the single panel in width being more suitable to such a door than the double one shown in the latter's design. The small window shown in section at line of capping of wainscotting would, we think, be better either larger or at least placed free from wainscotting, in which case the trim could be made as indicated in the elevation. Rendering is carefully done, and the sheet is nicely arranged, but we think it would be better if the author had taken the two pages permitted by the conditions to show his design.



CHAPEL ST. JAMES' CEMETERY, TORONTO.—(TORONTO ARCHITECTURAL EIGHTEEN CLUB JUNIOR COMPETITION IN RENDERING FROM PHOTO.) FIRST PRIZE, HECTOR A. PAYNE, TORONTO.

"Jack."—This drawing, which we place fourth, is referred to above. Its general defect, both in design and rendering is "fussiness". The head-piece of interior door and window casings would be much better if higher, and so arranged that the picture mould would mitre with its cornice mould or at least stop against it.

"Check" and "Plus".—Of the two last designs, that signed "Check" is somewhat the better, but neither esigner seems to have taken the problem seriously, either from inexperience or lack of industry, and both have overlooked the fact that the competition was for a complete vestibule.

[The names of the successful competitors in the competition for vestibule are: "Victor," (Mr. Willford A. Gagnon, 590 Temple building, Montreal,) awarded first position; "Torch and Wreath," (Mr. George C. Egg, 24 Tupper Street, Montreal), awarded 2nd position; "Drawing Pen," (Mr. Wm. G. Murray, Albion Building, London, Ont.,) awarded third position.—EDITOR C. A. & B.]

COMPETITION FOR PORCH.

"In Haste."—This is evidently intended for a stone porch. For a porch of its pretensions, the foundation looks altogether inadequate, and should have had plinth and cap moulding. The balustrade over cornice is too heavy, the introduction of the panels flanking the posts increasing this defect. The parapets of steps lack grace, through want of proper ramps and want of thought in design of pedestals. The rendering of section shows some care, but the plan and perspective are evidently hurried work. The projection of the shadows in latter are incorrect and line work unsatisfactory. Although we place the design first, we think it is to be regretted that the author did not devote more time to its perfection.

"Gains" is placed second, as the design, while rather that of a verandah than that of a porch, shows a good knowledge, both of construction and design. The scheme of the heavy projecting eaves, and the general simplicity of outline and detail, are commendable. As the frieze would of necessity be "built up" the arched soffit would be unsatisfactory and would seem to be an attempt to get the effect of stone in a wood construction. The rendering has little character and indicates lack of practice, the tree and foreground being very scratchy.

"Dodeka," who is given third place, shows a plan which is original but hardly commendable. The jutting

of vestibule into porch is a serious defect, and takes away from the usefulness of the floor space. The general character of the design is simple and pleasing and shows an appreciation of the natural use of materials employed. It also has a domestic feeling, which is appropriate. The rendering, though somewhat rough and careless, is fairly effective.

"The Imp" shows a cleanly executed drawing, without exhibiting much knowledge of effective line work, particularly in the shadows under porch and the trees in the distance. The plan itself deserves special mention, being probably the best sent in, the steps directly opposite the doorway leaving the octagonal space available for use, without being interrupted by the traffic to the front door.

"Ajacks" (Ajax?)—This plan would be improved by giving more projection in front of house, but is radically defective in that traffic from steps to door leaves balance of floor space of little use. As to design, the idea is good, but not backed up by sufficient display of knowledge of classic details, as shown by omitting abacus of caps in elevation, and although the Ionic order seems intended, the cornice is altogether too radical a departure from accepted forms.

GRANT HELLIWELL
JOHN GEMMELL
A. H. GREGG
} O. A. A. Committee.

[The names of successful competitors in the competition for porch are :—"In Haste" (Mr. Wilfrid A. Gagnon, 509 Temple Building, Montreal), awarded first place ; "Gains," (Mr. D. W. F. Nichols, 28 Toronto street, Toronto), awarded second place ; "Dodeka," Mr. W. F. Sheppard, 28 Toronto street, Toronto), awarded third place.—Editor C. A. & B.]

ORGANIZATION OF STUDENTS.

AT a meeting held a fortnight ago an organization of the architectural students in Toronto was effected, and the following officers appointed : President, D. W. Nicholls ; vice-president, E. H. Russell ; secretary-treasurer, A. M. Weir, 225 Clinton street.

A second meeting was held on the 5th inst., when after disposing of some routine business, the students attended in a body the lecture given by Mr. Kelsey under the auspices of the Toronto Architectural Eighteen Club.

A third meeting was held on the 12th inst., when a small summer cottage was set as the subject for design by the members, Mr. J. P. Hynes acting as critic. At this meeting it was decided that the members would attend and support the studio work under the auspices of the Toronto Architectural Eighteen Club. It was also decided to request the editor of the CANADIAN ARCHITECT AND BUILDER to give greater attention to the Students Column in that publication, and that the club would support any competition for students which might from time to time be conducted by the CANADIAN ARCHITECT AND BUILDER.

A method of keeping track of the names of the colors in a tin color box is to paste upon the flap each of the labels. The colors and labels will bear a relative position to one another. When the case is used this idea is a good one but a better scheme is to paste the label to the pan, then the color tells its own name.

Draughtsmen experience an annoyance sometimes by having their Indian inks upset. This bother may be overcome by making a little wooden stand in which are bored a number of holes comparing with the number of colored inks used.

MR. F. S. BAKER.

Mr. F. S. Baker, first vice-president of the Ontario Association of Architects, has recently been elected a Fellow of the Royal Institute of British Architects. Mr. Baker is the first Canadian to receive this honor.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

A special general meeting of the Province of Quebec Association of Architects was held last month in the association's rooms, 112 Mansfield street, when several amendments to the by-laws were adopted. The chair was occupied by Mr. Jos. Venne, the vice-president. There were present: Prof. Capper, Messrs. Alcide Chausse, J. S. Archibald, A. H. Lapierre, L. A. Amos, C. Dufort, M. Helbronner, A. C. Hutchison, G. N. Hutchison, Raoul Lacroix, R. P. Lemay, Quebec, J. P. Ouellet, Quebec, George W. Wood, Eugene Payette and Alp. Venne.

Before proceeding to the business of the evening

MR. F. S. BAKER,
First Vice- President Ontario Association of Architects.

this resolution was passed, read by Prof. Capper, all members standing :

Resolved : That the Province of Quebec Association of Architects expresses its deep grief at the sad tidings received of the death of Victoria, Queen and Empress, the beloved sovereign of this Empire, recording its profound sense of the national loss that has befallen all who share in the noble heritage bequeathed to her people by her long and blameless life of beneficient constitutional rule."

The date of the annual meeting was changed from September to January, which was considered to be a more convenient date, as the books of the association are closed on December 31st. The council will meet twice a month, first and third Tuesdays, instead of once, as heretofore. Examinations will take place both in Montreal and Quebec, if there are candidates in each place.

The twenty second annual exhibition of the Royal Canadian Academy of Art will be held in the galleries of the Ontario Society of Architects, Toronto, on April 12th. An effort will be made to send a representative collection of Canadian art to the Pan American Exhibition at Buffalo.

Mr. Richard Dinnis, the well known builder, of Toronto, delivered a lecture on the 8th inst., in the Beverley Street Baptist church in that city, on "Rambles in Italy." The lecture, which was illustrated by stereopticon views, was highly interesting and greatly appreciated.

ONTARIO ASSOCIATION OF ARCHITECTS

PROCEEDINGS OF THE ANNUAL CONVENTION HELD IN THE ROOMS OF THE ASSOCIATION, 94 KING STREET WEST, TORONTO, JANUARY 29TH AND 30TH, 1901.

The following members were present : Mr. A. Frank Wickson, President (in the chair), and Messrs. Grant Helliwell, A. E. Paull, D. B. Dick, M. B. Aylesworth, F. F. Saunders, Robert M. Ogilvie, George W. Gouinlock, Edmund Burke, J. Wilson Gray, John Kay, Laurence Munro, W. Frye Colwill, S. H. Townsend, A. H. Gregg, John Gemmell, W. A. Langton, F. S. Baker, W. R. Gregg, C. H. C. Wright, H. B. Gordon, Mark Hall, W. L. Symons, J. E. Belcher, R. J. Edwards, Alfred E. Boultbee, C. H. Bishop, George R. Harper and Charles F. Wagner.

The proceeedings were opened at 2.30 p.m., Tuesday, 29th, when the minutes of the last meeting were read and approved.

The President : Before taking up the business on the programme there is a resolution to come before us. I think there is no one in this room who has not known what it is to have the Queen as their sovereign ever since they can remember anything. And long as her reign has been there has never been any time or any occasion when we could not feel that it was a privilege to be living under it. While I think there is no thought of sending any communication from us, it has been thought that it would be a good thing if we had a resolution placed on the book referring to the death of our sovereign.

Mr. Dick read the following resolution which was carried by a standing vote in silence :

"That the members of the O.A.A., in convention assembled, desire to place upon record their sense of the great loss which the British Empire and the world have sustained through the death of the illustrious sovereign who, during the lifetime of two generations, occupied the throne of the British Empire, and by her irreproachable personal character, her womanly graciousness and sympathy, her queenly dignity, and her devotion to public duty, adorned her high station, and gave a name to that glorious epoch which has been the greatest in scientific invention and discovery since the beginning of history, and which will be known to all time as "The Victorian Era." They also desire to express their deep sympathy with the members of the royal family in their great personal sorrow for the loss of their beloved head."

The President, Mr. Wickson, then read his address :

PRESIDENT'S ADDRESS.

GENTLEMEN,—The Council of 1900 having bestowed on me the honor of the presidency of the Association, the responsibility has naturally rested on me of preparing and reading the conventional president's address which, by the way, will be somewhat shorter than those of my predecessors, as the registrar is to embody in his report a fuller account of the doings of the Council than has usually been done heretofore, and in addition to this several important committees are to report separately.

The measure of success during the past year, though less perhaps than we aimed at, will be seen to be considerable, and is due mainly to the indefatigable efforts of the various committees, and I desire to take this opportunity of thanking the members of these committees for the loyal manner in which they have stuck to the work entrusted to them, faced all the problems confronting them and assisted the president through the year.

As most of you know the results do not usually indicate the amount of hard work in connection with managing bodies such as councils and committees of a council, for as in the planning of a building, it is so simple—when it's done. The members of this Council as a Council have given much time to the thoughtful consideration of the matters before them in addition to their work on the various committees and sub-committees in connection with it. As an illustration of this we might instance the preparation of our new tariff. The committee appointed to attend to this gave every consideration to it, comparing all sorts of tariffs one with another, and then finally recommended the adoption of the American one in its entirety. We then held two meetings of the Council, each prolonged till well towards midnight, in discussing this report, and only those on the Council will have any idea of the difficulties we met with in the settling of this schedule of professional fees. The size numerically of our country, cities and towns, practically necessitated some changes, and to make these changes suit the members in the largest of our cities, in the small cities and in the towns, was no easy matter. I believe we have a good tariff now, with possibly only one mistake, and that was the result of too great a care for our clients' interests. Allow me to beg any member who may feel dissatisfied with this tariff or any part of it to remember that there is a great diversity of interests to be considered and the final outcome had to be one suitable to the largest possible number without regard to individual wishes in the matter.

It must be a source of considerable pride to us all that we have at last been able to meet in our own rooms, and the rooms committee and monthly meetings committee will report as to the furnishing of the apartments and as to the uses to which they have already been put.

It is to be hoped that our library now easily accessible will be freely used by the members and also such periodicals as we may from time to time supply ourselves with. There will be some exchanges which may prove exceedingly useful in the way of directing us where to find articles pertaining to special subjects on which information may be sought.

As to the ases of the rooms, there will, it is expected, be a great deal of social benefit resulting from the possession of a common meeting ground. Ihave not the slightest hesitation in saying that personally I expect in these rooms to make valued friendships and to enjoy meetings which if held elsewhere would lack much of the enthusiasm which will inevitably be aroused in such surroundings, but there will be, I trust, no dissenting voice when it is said that our professional home should, like the machinery of our whole organization, be used for the great end which should animate us all, viz., that of architectural education. This is an age of education and in many lines in which a few years ago it would have been con sidered quite unneccessary, facilities are now afforded and taken advantage of for a theoretical training where only "practical ex-perience" was considered necessary.

For general educational purposes in the wake of the kindergarten comes the manual training, and for the special benefit of the artizan there are the technical schools; other professions have long had systematic courses of study, and in our own profession there are abroad many inducements and opportunities for a higher and more thorough training than the generation preceding ours would scarcely have dreamed of.

There is a vitality in the architecture of the present, perhaps we might say the whole world over, and this is noticeable to no small degree in the great country beside us ; we should therefore not be lagging in the struggle to also emerge from the foggy atmosphere of past methods of study in our profession and to obtain a better basis to work on in the future, and as far as possible our rooms as well as our various efforts should be made to conserve to this end.

In President Emerson's address to the R.I.B.A., which possibly most of you have read, he recognizes certain necessities and problems with which we also are face to face. He admits the necessity for methodical training, though he believes it might be given with possibly less of what might be termed the weariness of the French training. He refers to the need for trained familiarity with work of the past so that an architect gifted with any power of freedom of thought and expression should, while avoiding weariness, be able to avoid faults of proportion and detail so common to the untrained and so exasperating to the trained.

The French themselves and those who can afford to become French temporarily have a great advantage in the well known school of architecture, though America is advancing with such strides in the study of this art that the incentive to go to France is becoming less each year, the influence of the former having permeated the latter to a great extent, and as Mr. Ernest Flagg says, that although "architects" are still striving for the extraordinarily original, and deprecate the Frenchifying of American architecture, students are working along the correct and same lines of study fully convinced that the logical reasoning taught by the great French masters is the proper preparation for their work.

In view of this widespread tendency to progress in the proper study of architecture and because there may be many of our own countrymen who cannot attend either the French or American schools, and because there may be others who could go but who are worth keeping in Canada for a large part of their time, we cannot turn our attention too quickly and too faithfully to any phases of the work which may be within our reach.

The report of the Educational Committee puts before you the scheme we have decided upon—a scheme formulated by a joint committee composed of some members of our Association and some from the Toronto Eighteen Club, and though the inauguration of the scheme has hung fire it is what we are looking forward to as one of the main works of our Association. In this connection I would like to mention our appreciation of the way in which the School of Practical Science has sought through our valued member, Mr. C. H. C. Wright, to adapt itself to our wants in spite of the fact that it like all such schools does neither advise nor like "special" courses, and the Council of our Association is heartily desirous of seeing that institution made use of in the near future by a large number of students.

To those who are neither my seniors in years nor in practice I would like to suggest that we practising architects do not leave progress for draughtsmen and students alone, but that we also keep abreast of the times and perhaps study sedateness and reasonableness to a greater extent than some of us have done, although it is apparent to everyone that this is more difficult in a country where there are few monumental buildings of any kind and particularly of the domestic type.

Buffalo's great Pan-American Exhibition will be a boon professionally, and I presume will be visited by every architect in these parts of Canada within reasonable distance of our, comparatively speaking, neighbor city. Although in no way an agent of the great Fair I would urge every one to take advantage of this latest opportunity to study architecture on a large scale and in the form of object lessons. From a preliminary canter around the grounds it would seem to me that America has after first whipping Spain turned around and stolen her clothes and is wearing them in a very attractive manner.

In Mr. Emerson's address, above referred to, he, recognizing the same difficulties with which we have to contend, admits the necessity for legislation, something I understand hitherto opposed by the R.I.R.A.

The old story of unsatisfactory competitions has once more, like the ditches and watercourses act in our legislature, to be resuscitated. In one instance an effort was made by a couple of members of the Association to have better conditions fixed, but the result was only a promise to have two experts from our Association retained to act with the Board in their decision and the emoluments offered, much too insignificant, were not enlarged.

In England competitions for public buildings have to some extent been abandoned, but not altogether, as the competition for the London council's great works has proved; the comparative similarity in style amongst the competitors was both noticeable and instructive.

It is a matter for regret that there seems to be a tendency for private individuals to seek to obtain competitive sketches for small work—something that I believe cannot be too emphatically discouraged by our members.

After much discussion a revised model contract was agreed on by a committee of the Association and a committee of the builders, approved of by our Council and then rejected by the Builders' Exchange.

In the matter of the consolidation of the city by-laws our registrar has been promised a copy of those parts relating to the building laws, which will be submitted to the committee when received.

In conclusion allow me to express the hope that this convention will be one pleasant and useful, and to the visiting members particularly we extend a hearty welcome. I believe there is possibly less need just now to urge unanimity than for a long time past as we are all looking forward in confidence to a splendid future for our Association.

Mr. Baker read the Treasurer's report, which on motion of Mr. Gray, seconded by Mr. Burke, was adopted :

TREASURER'S ANNUAL STATEMENT, JANUARY, 1901.

RECEIPTS.

4 Registration fees	$60.00	
Students' registration fees	6.00	
Students' examination fees	10.00	
Members' annual fees, class I.	195.00	
" " " " III.	21.00	
" " " " V.	16.00	
" " " " VI.	4.00	
" " " " VII.	20.00	
Engineers, for share of furniture	26.50	
Interest on bank balance, 1900	33.60	$392.10
Balance from 1899		995.25
		$1387.35

EXPENDITURE.

W. R. Gregg, Registrar	$100.00	
W. R. Gregg, disbursements	25.00	
Printing (including schedule of charges)	44.75	
R. M. Williams, engrossing	11.75	
Duffet Co., chairs for convention	3.00	
Nordheimer Co., piano Dec'r meeting	2.25	
F. Henry, expenses, Council meeting	7.00	
Cromhie, Worrell & Gwynne, account	4.00	
C. H. Mortimer, CANADIAN ARCHITECT AND BUILDER account	22.00	
Discount, Collingwood cheque	.15	
Furniture for rooms	131.89	
Kay & Banks, insurance premium	5.36	
Electric light account	1.09	$358.24
Balance on hand		1029.11
		$1387.35

We have examined the books, vouchers, etc., in the hands of the Treasurer, and certify that the above is a correct statement thereof.

JOHN GEMMELL }
C. H. BISHOP } Auditors.

All accounts which have been presented have been paid. The accompanying statement shows that the affairs of the Association are in a satisfactory condition, the ordinary expenditure for the year being nearly $100.00 less than last year, while the ordinary receipts are about $135.00 greater. After most of the furniture necessary for the rooms has been paid for the balance on hand is $1029.11 or $33.86 more than last year's balance, while the furniture remains an asset.

Respectfully submitted,
F. S. BAKER, Treasurer.

On motion of Mr. J. Wilson Gray, seconded by Mr. E. Burke, this report was received and adopted.

Mr. William R. Gregg then read the registrar's report as follows :—

REGISTRAR'S REPORT.

The Council has been in session fifteen times since last annual meeting. In the former part of the year the meetings took place in Mr. Langton's office, Mr. Wickson's office, the School of Practical Science, Mr. Townsend's office, and the Registrar's office, but since Nov. 13th in the Association Rooms.

After necessary notice of motion, a resolution was passed by the Council on 12th March that "Architects who have not registered or passed the examinations prescribed by the Association, but who otherwise satisfy the requirements of the Ontario Architects' Act and who apply before Dec. 31st, 1900, may be admitted without passing the examinations prescribed for students, if the Council after taking such steps as may be necessary to satisfy themselves of the qualifications of applicants, are agreed as to their fitness."

This motion was published twice in the CANADIAN ARCHITECT AND BUILDER and a number of applications were received before the end of the year, and as a result the Council has accepted 12 architects as qualified to be registered as members of the Association, each upon recommendation of the Board of Examiners.

In accordance with a motion passed in the convention of 1898 the names of members in arrears for a period further back than 1898 are omitted from the annual list of members which is now submitted. Each member whose name has been dropped in this way has been first notified by registered letter that his name would be omitted if arrears are not paid up to this point. The membership now is; 2 Honorary members, 33 Resident members, 27 Non-resident members, 5 Travelling members, Total 67 members.

A certificate of membership is now ready to be issued, intended for display in the offices of members, who are reminded that a motion was passed at last annual meeting requesting the adoption of the words "Member of the Ontario Association of Architects," as our distinguishing title.

One student registered in 1900. Examination was held in April. One student passed the second examination creditably.

The Council has jointly with the Engineers' Club of Toronto completed the arrangements in regard to the lease of these rooms, for a period of three years from 15th Nov., 1900, at a rental of $300 per annum, heating and caretaking included, of which this Association pays $150.

Messrs. Gemmell, Pearson and Townsend are the Committee in charge of their furnishing and management.

The furniture and other property of the Association has been insured for $500.

A committee, consisting of Messrs. Dick, Darling, Townsend, Denison, and Curry was appointed by the Council to draw up a tariff of fees as a guide to members in making charges for professional services, and this committee reported, recommending that the present tariff of the American Institute of Architects should be adopted. Copies of this tariff were procured from the secretary and carefully considered by the Council and certain minor changes were made, after which it was adopted. Five thousand copies have been printed; of which twenty-five have been sent to each member of the Association and the remainder kept for future distribution.

The Council, by request, appointed a committee to meet with the Builders' Exchange of Toronto and consider the question of improvement of the form of contract now in use, which is called the "Model Contract." After a number of meetings a report of changes recommended by our committee was submitted to the Council and adopted. No form of contract for general use has yet been printed embodying these improvements.

The library has been in the hands of a committee, Mr. A. H. Gregg, chairman.

It was found impossible to issue a Report of the proceedings in separate form in 1900 but it has been resolved that it shall be done this year at the close of the present Convention, and an Editing Committee has the matter in hand, Mr. M.B. Aylesworth, chairman.

It was resolved by the Council, as was proposed at the last annual meeting, that a regular monthly meeting should be held in the rooms upon the first Tuesday after the tenth of each month excepting May, June, July, and August, and a standing committee was appointed to arrange the programme of each meeting. Mr. F. S. Baker is chairman.

The question of Education of Students was given a great deal of consideration by the joint committee with members of the Toronto Architectural Eighteen Club, and a report presented to the Council which was further considered by the Council's Committee on Education, and a new curriculum was prepared and received by the Council, and after having been published in the CANADIAN ARCHITECT AND BUILDER in August was finally adopted on 15th January 1901, with the condition that the clause requiring matriculation of students before entering should be allowed to stand in abeyance until such time as it shall be found practicable to enforce it. The former curriculum has been kept in force until the present time, and it remains for the Council of 1901 to work out the details of the new scheme.

The R. I. B. A. has arranged to hold annual examinations in Canada, and our Council has appointed Messrs. Townsend and Langton as examiners to act with others appointed by the Quebec Association of Architects.

An advertisement in the CANADIAN ARCHITECT AND BUILDER gives further particulars of these Examinations.

Mr. S. G. Curry has written the registrar stating that he holds a sum of about $250, funds which the Toronto Architectural Guild before it disbanded decided to hand over to the Ontario Association of Architects under certain conditions : to be invested and held in trust for purposes stated in the conditions of the gift. The Council has not yet received fuller information on the matter ; but will be pleased to carry out the conditions of the bequest.

After notice of motion a new by-law has been passed to-day by Council, as follows :—Members who have resigned or failed to renew their membership shall if they resume membership pay a fee of $15 dollars which shall include the annual fee for the year current at the time of resumption of membership.

Mr. Burke : With reference to insurance, is there any provision made for protecting our documents, minutes

&c. ? No insurance could replace the loss if a fire should destroy our documents.

Mr. Gregg : The insurance policy reads "books, documents, &c." I do not remember the exact words, but it mentions the documents.

Mr. Burke : What I mean is, is there any provision for preserving these from fire ?

The President : There is nothing at the present time.

Mr. Baker : Perhaps Mr. Chairman the Rooms Committee will tell us. The original plan shows a fire-proof vault, or two of them, in fact, one for the engineers and one for the architects. Of course the arrangement is very different from that, but there may be some explanation of it.

The President : Perhaps in the report from the Rooms Committee that will be mentioned.

The Registrar's report was adopted on motion of Mr. Baker, seconded by Mr. Townsend.

Mr. Langton : I would like to know Mr. President why there is this vagueness about the bequest from the Guild. No one seems to know what the conditions are.

Mr. W. R. Gregg : I will read the letter.

WM. R. GREGG, Esq., 61 Victoria St., City,

Dear Sir,—I hold about $250.00 of funds which the Toronto Architectural Guild before it disbanded decided to hand over to the Ontario Architectural Association under certain conditions.

These funds can be handed over as soon as the necessary arrangements are made to carry out the conditions of the bequest.

It will be necessary for the Council of the Association to accept the bequest under the conditions named and to make arrangements to invest same in a separate and distinct fund to be held in trust for the purposes stated in the conditions of gift.

The above amount is not all that should be received, as there should be a further payment on account of the Farmers' Loan Company's assets.

Yours truly,
S. G. CURRY.

Mr. Langton : Yes, but what are the conditions? When was that letter received ?

Mr. W. R. Gregg : That letter was received on the 19th of October. I answered that the Council would be pleased to carry out the conditions if they would let them know them, but I received no reply.

Mr. Langton : I think Mr. Curry ought to let us know what the conditions are. I move that Mr. Curry be written to at once and asked to hand over the money. As we appear to have accepted the conditions without question he ought to give up the fund.

Mr. Burke : Are these conditions not in the Association minute book ?

Mr. Baker : I would like to ask that the minutes of the Council on that matter be read.

Mr. W. R. Gregg read : "Resolved that the Council of the Association gratefully accepts the bequest of the Toronto Architectural Guild and would be glad to have the conditions submitted to it."

The President : Mr. Langton has moved that Mr. Curry be asked to state the conditions and send us the money.

Mr. W. R. Gregg stated this had already been done.

Mr. Baker : Could not Mr. Curry be again asked to send the conditions ?

Mr. Helliwell seconded Mr. Langton's motion.

The President : It has been moved by Mr. Langton, seconded by Mr. Helliwell that Mr. Curry be formally asked to send us the conditions, so that we may know what we are to do.

The motion was carried.

Mr. Baker, convener of the Monthly Meeting Committee then reported : I think the Agenda shows pretty well what the Monthly Meeting Committee has been doing. The Committee will immediately prepare the programme for the next monthly meeting. The meeting which is set forth on this Agenda paper, I think looks rather hopeful, as good as any we have ever had, and I think we will look forward to the monthly meetings as they follow one after another. It was thought well at one time to have the programme announced at the previous meeting. But it was stated that if we gave the programme out a long time ahead, the men who were to read papers would forget about it, and not appreciate the long time given them for preparation. There is one thing I think should be established—a night when the members could come to the rooms and meet each other—something in the nature of a club. We have had some very nice social gatherings. We cannot expect to get all the city members out at once, but we could have several pleasant evenings. I think a motion might be made here if you think well of this idea.

The President : I think this is a matter for the Meeting Committee to take up.

Mr. Baker : I think it should be discussed by the Convention. I move that Saturday night be decided upon as a night upon which members would resort to the Rooms, especially with a view to meeting other members.

Mr. W. R. Gregg : I think it is rather a pity to decide suddenly without the Committee's consideration. It occurs to me that it should be on a night not a Monday or Saturday, so that outside members could drop in and meet Toronto members.

The President : I suggest that the matter be allowed to stand awhile and be brought up later. I think Mr. Baker omitted in his report the pleasure which we had of listening to an address by Rev. Dr. Clarke, of Trinity University, an address which I think everybody enjoyed.

Mr. Gemmell was then asked to read the report of the Rooms Committee, but said that the report would necessarily be largely financial, and the accounts were not yet all received.

Mr. Langton in Mr. Pearson's absence read the report of the Library Committee :

The library was kept for the early part of the year in Mr. W. A. Langton's office, later in the office of Messrs. Langley & Langley, and in November it was moved to the Association Rooms.

The Association is indebted to Mr. Henry Langley for his generous donation of 61 bound volumes of the "Building News" and other magazines, besides a large number of unbound copies of the same, and also to Mr. Mark Hall for seven years of the "Canadian Architect and Builder."

In addition to the above, the library contains 77 volumes of architectural works, which are available at any time by members of the Association and registered students.

The duties of the librarian have been performed in an informal manner by the Library Committee during the year, and it seems now desirable that a regular librarian be appointed.

Two books, Baldwin's Steam Heating, and Viollet-le-Duc's Habitations of Man, are missing.

Offers of further donations of books have been made to the Association, and the Committee recommends that new books be purchased from time to time, especially text books which would be of use to the student, and such recent publications on heating, ventilation, etc., as would be of service to the busy architect.

The Committee also recommend that the file of the "Canadian Architect and Builder" be completed and bound in yearly volumes."

This report was received and adopted on motion of Mr. Gouinlock, seconded by Mr. Langton.

Mr. Burke was asked to make a report with reference to the Chapter.

Mr. Burke : The Chapter is dead ; that is all I know about it.

The President : It is scarcely so dead as all that. I thought that they met and appointed representatives to the Technical School Board, which is practically all there is left for it to do since the Association has established monthly meetings.

Mr. Burke : I forgot to mention that we met and appointed members to the Technical School Board. We have also been keeping it alive by holding lunches here, and it is a question perhaps, if we could not keep up these lunches and have all the members attend.

Mr. A. H. Gregg read the report of the Educational Committee :

REPORT OF EDUCATIONAL COMMITTEE.

A summary of the work of the Educational Committee was published in the August number of the CANADIAN ARCHITECT AND BUILDER.

The Committees' report has been adopted by the Council, with the condition that the requirement that students must be matriculants be not enforced for the present, although this was deemed a desirable feature, which should be introduced as soon as possible.

Following is the curriculum as arranged by the Committee:

GENERAL REQUIREMENTS FOR ADMISSION.

Students to have passed Matriculation and to be articled for five years with architect.

(or) Students who have graduated from School of Practical Science shall be required to serve only three years with architect

one of which three years may be served during vacations of said school.

Course of study to include three branches.

"A" Scientific. Subjects in this branch are taught at the School of Practical Science.

"B" Business or Craft Training. Including subjects in which student should become proficient in his regular office work, supplemented by study of technical books as recommended.

"C" Design. A three years "Studio" course occupying three months (November, December, January) in each year.

Studio work to be taken in Association Rooms, during afternoon or evening, as convenient, under patronage of practising architects.

Examinations to be held each year in Courses A. and B.

In the studio work a progression by mentions will be required.

1 Year "A" Analytical geometry, euclid, trigonometry, algebra, history of architecture, chemistry.

2 Year "A" Calcus, history of architecture, dynamics, statics, descriptive geometry.

"B" Elements of construction, technical terms (as applied to practical architecture), practical knowledge of building trades.

3 Year "A" Descriptive geometry, heat and optics, strength of materials, applied chemistry.

"B" Practical knowledge of building trades, foundations, structural iron work.

"C" Preliminary studio work (drawing of classic detail and shadows).

4 Year "A" Hydrostatics, mineralogy and geology, constructive design.

"B" Steel and iron construction, nature and properties of materials.

"C" Studio work.

5 Year "A" Hydraulics, compound stress, mineralogy and geology, applied chemistry, sanitary science.

"B" Architectural jurisprudence, (practical) heat and ventilation, (practical) sanitary science.

"C" Studio work.

Probably the most successful school for architectural design, that the world has ever known is the Ecole des Beaux Arts at Paris, and the following notes taken from a series of papers by Ernest Flagg, may be of interest :

This school is supported by the government, and to obtain the privileges of the architectural course the following "admissables" must first be passed.

(1) Architectural Composition. In this examination 12 hours allotted to the study of given problems in design, plan, section and elevation to be drawn.

(2) Modelling in clay, for which 8 hours are allowed to reproduce in clay, a plaster cast of a piece of ornament.

(3) Drawing from the Antique.

Should the prospective pupil prove himselt proficient in these subjects, he may then try the examinations in descriptive Geometry, Algebra, Arithmetic and History, (general) and if successful in passing these, he may then be enrolled as a pupil, and enter the atelier of his choice.

The school is divided into 1st and 2nd classes. Entrance to the 1st class is obtained by gaining a required number of honorable mentions in the following subjects: Theory of architecture, history of architecture, descriptive geometry, steretomy, perspective archaeology, drawing of ornament, drawing of the human figure and modelling in clay.

Upon attaining to the 1st class and obtaining a certain number of honorable mentions therein, he is allowed to choose a trial programme for the design of some monumental building, and should he be successful in this he receives his diploma from the government and becomes a full fledged architect.

During the course great stress is laid on theory of architecture, which occupies the greater part of the student's time. Construction takes the best part of a year.

In the theory of architecture, six projects are given each year, For these, a preliminary sketch is made at the school and 12 hours allowed to show plan, section and elevation, which may be very vague and drawn to a small scale.

This sketch must then be approved by the student's patron, then rendered, i. e. studied, and full drawings made.

The eteliers are the most noteworthy features of the Ecole. These are under the supervision of practicising architects who have won distinction in the profession and who visit the studios two afternoons a week to give criticisms and advice.

Mr. Baker : Has anything definite been done abont arranging classes to be held in these rooms?

The President : There is a Committee on studio work (that is the work to be done in these rooms). This Committee has not at present time prepared a report. They have not actually started the classes. I wrote to the Convener the other day and told him I thought it would be well to start now and not let this winter go by with nothing done.

Mr. Helliwell : A report like that is very comprehensive, and is rather a big thing for a Convention like this to attack. Has the Committee in charge any recommendations in regard to the report?

Mr. A. H. Gregg : I may say that the committee that prepared this report is really defunct. I simply read it now that it might be laid before the convention but it is expected that the convention will form other committees to carry out the work this committee started. The committee appointed was Mr. Edmund Burke, Mr. C. H. C. Wright, Mr. Eden Smith and myself. A great deal of time was spent in comparing the past curriculum of the Association and the School of Practical Science curriculum, and in trying to improve ours so as to get a more complete course of study. In the first place the scientific course that all architects ought to go through was considered by the committee as best taken at a school under professors that make such work their business, and the School of Practical Science was that school for Ontario. The regular course there is three years. As a majority of students intending to become architects start their career in an architect's office, provision has been made that such students can take a course at the School of Science by spreading their studies over five years. In this way a student in an architect's office by obtaining leave of absence for an hour or so a day can attend the classes at the school. It is already established by our Act that a graduate of the School of Practical Science need only serve three years in an architect's office and if we press the educational requirements upon our students no doubt many will see the advantage of disposing of the question by taking a full course at the school. But I am speaking chiefly of the way in which the ordinary student will be affected. Of course such a departure as the proposed curriculum, is a very important one. Probably there will be changes made, and I think that the Council considers that the educational work of the Association is probably the most important work of next year, and it is certainly most important that a strong Educational Committee be formed.

Mr. A. H. Gregg then read a brief account of the manner in which the architectural course at the Ecole des Beaux Art, at Paris, is carried on.

Mr. Burke : Mr. Gregg, I think has forgotten to mention that there was an alternative proposition, that is, that if it should prove impossible to carry out such a scheme of having our pupils spend one or two hours a day at the School of Science, that the next best method would be to have our students attend the mathematical classes at the Technical School. That seems to be the only other feasible method that could be adopted, for ordinary students.

A Member : Have we any recommendations from the council with reference to this report?

The President : The Council has adopted that report.

A Member : It is then for us to accept that report and to appoint a committee.

Mr. Paull : What is this committee to be appointed to do?

The President : This committee is to take up the work of this scheme of education.

Mr. Burke : I think this is a matter which concerns the whole Association, for if we are not prepared to have our students go up to the School of Science for lectures, it is really no use to have the committee appointed to forward the scheme.

The President : I would like to hear from members of the Association, particularly those who happen to have students now. With reference to this scheme of education, thereis one thing which the committee was confrontedwith. That is, the students who are in cities and towns outside of Toronto. But as it was impossible to get a system of education which could be locally applied it was thought that there was no alternative but to get one which they would have to come to Toronto to take. Students in other professions have to come to Toronto for their education, and architectural students would soon get accustomed to having to come also. The only way is to establish the means of education, and that would bring them to it. I think this Convention ought to express it's approval or disapproval of this scheme, if the members have been able to digest this suggestion.

Mr. Langton : I suggest that Mr. Wright be asked to explain the school work.

Mr. Wright : The educational scheme which is proposed, classifies the training of an architect under the three heads, Scientific, Practical, and Design, and it is the intention inthis report to allow any candidate to elect tot ake them up in the order named or simultaneously. If he elects the former he attends a school of Applied Science for three years, following which he spends two years in an office where he obtains the practical training, while in the evenings he attends the classes in studio work which gives him his training in design. In case the student selects the second method he is required to spend five years in an office and on an average about two hours a day in the scientific subjects taught at the School of Practical Science. These subjects I may say include those necessary for scientific and safe building and have been arranged systematically, (the simple laeding to the more complex) to cover the entire course of five years. As before he spends his evenings under the care of patrons of this Association studying design. It would seem to me that the two main difficulties from the point of view of the practising architect are, 1st to obtain pupils of a standing equivalent to university matriculation, and 2nd, to provide the time during office hours necessary for the scientific subjects when the work is taken simultaneously. I believe however that these and other difficulties will adjust themselves in time and both pupils and principals will be benefited.

Mr. Helliwell : Mr. Chairman there is one thing possible that might be done. A thorough canvass of the offices might be made to see if students would accept the motion as a whole or adopt this course, then a committee might be formed to arrange classes and appoint teachers.

Mr. Gemmell : I think the convention ought to pass upon the scheme, and the details of the scheme be arranged by the committee or by the Council. I think it is the duty of the convention to appoint patrons to lecture on the theory of architecture and practice, and on design, &c. I think they ought to adopt that. They may not be able to live up to it altogether, but I think they ought to adopt it, or else go backward.

Mr. Langton : I think that another course might be taken than that suggested by Mr. Helliwell. It might be possible also to approach the question also from another way. Members of the Association who have students in their offices might make something more than an enquiry of them. Their relation to their students is parental and if they are in sympathy with the aims and methods of the Association they should prescribe its educational course as part of the work of studentship.

The President : As to the architects' willingness to lose the time of their students, I think the architects would be repaid for it in the extra value of the pupils. I know that the only experience which I have had with the School of Science pupils was a very satisfactory one. The gentleman whom I had in my office came from the school and it was only a very few days before it was evident that he was worth more than another man, and I think it would repay the architects to take this course. It might inconvenience them at first, but it would repay them in the end. I think we ought to keep in line with other professions, and we can only do it by a little sacrifice on our part.

Mr. Burke : I want to say in connection with what Mr. Wickson and Mr. Wright have said, I know a man who had been in the school and came into an office ; he was away behind another student who was in the office, but after being a year in the office the School of Science man forged away ahead of the man who was educated in the office.

Mr. Gemmell : I move that this Convention approve of the scheme to produce better education of students in connection with the School of Practical Science, and of the endeavor to establish departments of studio work and branches which are to be taught in the school.

Mr. Gray : That is exactly an adoption of this report.

Mr. Gouinlock : Mr. Chairman, I would like to know whether it is proposed that it should be compulsory for the members to allow their students to attend the school.

The President : If a member agreed to allow the student to take the course he would naturally have to give him the time to do it. I presume you mean though that as members of the Association, are we bound to? I do not think we could compel a man to take this course. I don't think the powers of the Association would enable us to write a member off the list because he refused to let the student take the course which we considered the proper one.

Mr. Baker : Before we put that motion I think I will suggest, just to test the feelings of the meeting, that this Convention advertise this scheme by fully reporting it in the CANADIAN ARCHITECT AND BUILDER, and that a request be made that all students who wish to take the course should send in their names to the Registrar before a certain date.

Mr. A. H. Gregg : The Committee's report has already been published in the CANADIAN ARCHITECT AND BUILDER, and a number of students have asked that something of that kind might be started. If he considers that too much to force on the members of the Association, that by-law can be changed ; that is all there is about that. And the studio work means classes in which local practising architects who are willing give their time to criticise and advise the students in their work and design as carried out in studios in New York and other cities. It is voluntary and we will have to find architects that are willing to do so.

Mr. Baker : I am very glad to hear that the students are ready to take up the work, and I think it only remains now for us to decide upon this scheme and to arrange classes and appoint teachers. I think it had better be put right on the shoulders of the Convention.

Mr. Wright : I think, Mr. Chairman, for the purposes of this discussion we might divide the students into two classes—1st, those who are registered and at work, and 2nd, those who may registrar during the coming years. If we are providing for this latter class I think the proper one to canvass is the architect and not the student. If you ask the student he will have the examinations made easy, while after he is through and becomes the architect he would make them hard. (Laughter.) There are a few advanced students in offices who will require special consideration if a scheme like this is carried out, and I am sure a number of the members of the Association are willing to grant the time to these men to help them in their difficulty. I am quite willing as far as I am concerned to help them with their advanced mathematics, and as far as their other work is concerned I am sure that they will get the necessary help. I think we should consider more especially those who are proposing to enter the profession and not those who are at work.

Mr. Burke : I agree with Mr. Wright and think the students should be recommended to brush up their studio work and endeavor to take up the School of Science work. Our plans for the future should be for future students. I have had several applications from students, and have recommended that course, but the guardians have not seen their way clear to go to the expense involved. I think we should make the matter of higher education a strong point with regard to students.

The President : I think the architects should look at it in that way. To a young man who applied to get into my office I pointed out both to him and his father that the only right way if they wanted him to become an architect was to follow our course of education.

Mr. Burke : I am glad to announce that there are fifteen or sixteen young men to meet to-night in my office for studio work, and all we have to do is to ask them and they will come right into a class for study.

Mr. W. R. Gregg : This system of studio work is one of the most important developments of architectural education. In the present time it is recognized that design is not learned by sitting down with a blank paper before you, and a blank brain, and trying to put a building on the paper. It is a matter of teaching the student to think and to do a thing in the proper way, and this studio work is as great a boon to architectural education as the kindergarten is to primary education.

Mr. Baker : Mr. Chairman, we are all perfectly agreed on these beautiful theories. Now what I would like to get at as usual is something practical. Could you not appoint a committee to report to-morrow to immediately arrange for getting to work in these rooms.

The President : There is one thing : first to get

the members to adopt this motion approving of this course.

The motion made by Mr. Gemmell was then seconded by Mr. Langton and carried by the meeting.

Mr. Langton : Mr. Chairman, the question is how to get the students. I would suggest that Mr. Baker's proposal of a committee to suggest the names of patrons before to-morrow morning, and consult them if possible, be carried out.

The President : In reference to this motion that we appoint a committee to see patrons, would it not clash with the committee which is appointed to carry this on ? think there will likely be a committee appointed to carry this on. Possibly their duties may dwindle down to seeing the patrons and arranging about the way these classes are to be held and that sort of thing. There is a Studio Committee existing at the present time consisting of Mr. Eden Smith, Mr. A. H. Gregg and Mr. Darling.

Mr. Gemmell : Are we not to understand Mr. A. H. Gregg to say that they have done their full duty and ask to be disbanded ?

Mr. A. H. Gregg : The principal thing is to settle whether we want as an Association to adopt such entrance examinations, and whether it is to be compulsory for all architects to require their students to go through the course. In my mind it is a great mistake to have any rules and by-laws that are not enforced. There is no use putting a by-law in the books saying that members of the Association are not to have unregistered students in their offices, unless they are prepared to enforce such a by-law.

Mr. Langton : We cannot force architects to do anything, but we can make a very good course of examinations, and it is to the advantage of the architect to make his students take it, and if he cannot make them take it it is to his advantage to get students who are willing to take it. The great thing is to make this curriculum so that students and architects will desire to support it. It strikes me that it will in time become necessary for students to take it, just as it is in Boston for students to take a course in the Massachusetts Institute of Technology. Were we to refer this back to a committee, Mr. Eden Smith, Mr. Gregg and Mr. Darling, there is only one thing for them to do ; the rest is done. We have the curriculum ; we have, as Mr. Gregg and Mr. Burke have said, students waiting to take it up. The only thing that remains is to select the patrons for the studio. This is all any committee can do if we refer it to them, and as Mr. Darling and Mr. Eden Smith are not here, to refer back to a committee of which they are members means a delay and a delay which is unnecessary, for we can appoint a committee of this convention which can make a selection of patrons and communicate with them to obtain their consent, so that before this convention breaks up we shall have the whole educational system settled. I therefore move that the President name a committee of the convention to appoint patrons, if possible to communicate with them to obtain their consent, and report to the meeting to-morrow.

Mr. Baker : I have much pleasure Mr. President in seconding Mr. Langton's motion that we do this thing right now. If to-morrow these names are brought before us and approved, why we can act. Let us do something, let us get ahead, we have got together now at this convention, and we have only to decide. Of course I know why the thing has been let slide for the past year, but courtesy does not demand anything further from us in that direction.

The motion was carried, and the President named as the Committee Messrs. A. H. Gregg, C.H.C. Wright, Eden Smith, E. Burke, S. H. Townsend and A. F. Wickson.

REPORT OF COMMITTEE IN CONNECTION WITH CERTIFICATE.

Mr. Baker : Mr. A. H. Gregg and myself were made a Committee to procure designs for a certificate of membership to be put in the possession of each of the members of the Association, to be retained by them as long as they remained members of the Association, and to be returned by them when they ceased to be members. The matter proved a very difficult one indeed. One or two designs were submitted by the architects, but none of them seemed to be desirable ; at the last moment when it seemed necessary to act, it was decided to ask Mr. A. H. Howard, who is a professional designer, to prepare a design, which was done. The certificate which you see on the wall here is the one. This design was not thought altogether satisfactory, but still it was accepted as the best we could get, and we ask the Convention to bear with it, and try and realize what a difficult subject it was to treat. I think it will be a certificate that every member will be glad to have. It certainly is a distinction to be a member of this Association, and none of us should hesitate to have this certificate hung in our offices.

The President read a letter from Mr. Taylor, Secretary R. I. B. A. examinations in Canada, and it was moved by Mr. Baker, seconded by Mr. A. H. Gregg and carried, that a circular be sent out to members calling attention to these examinations with a view to securing candidates.

Mr. Burke : Anybody who reads the by-laws of the Association will observe that a number of the by-laws have become practically obsolete. Would it not be well to remodel these by-laws and bring them up-to-date. We cannot hand the by-laws of the Association to any new member without misleading him ; I therefore move, seconded by Mr. Helliwell, that the Council revise the by-laws and have them printed before the next annual meeting.

Discussion ensured as to the need of revision in portions of the Act of Incorporation and the possibility of procuring such revision.

Mr. Burke moved that action in regard to the amendment of the Act be left to the discretion of the Council. Seconded by Mr. Baker, and carried by the meeting.

Mr. Baker moved that a circular be sent out in reference to the R. I. B. A. examinations, to the architects and members of the Association.

The President : I think some architects who might not read the notice in the CANADIAN ARCHITECT AND BUILDER might read the circular.

The motion was seconded by Mr. A. H. Gregg and carried.

WEDNESDAY'S PROCEEDINGS.

The President took the chair at 10:30.

The Committee appointed on the previous day to suggest the names of patrons for the studio work reported. After some discussion the report was adopted, with the following gentlemen appointed as patrons :—Messrs. Darling, Gemmell, Langton, Symons, Horwood and Eden Smith.

Mr. Burke : Are we to understand, Mr. Chairman, that absolutely no students except those in offices of members of the Association, will be eligible for studio work ?

Mr. Baker : Not unless they are registered students, of course.

Mr. A. H. Gregg : I think that is a question that should be left open for the present.

Mr. Baker : Before a student joins this class he should become a member of the Association. It is one of the ways we have of strengthening the Association.

The President : I think your idea is that a student outside the Association altogether should not be allowed to come in here and take the studio work without having become a member of the Association. I think that is an understood thing.

Mr. Burke : There is a case in my office. A School of Practical Science man, unable at present to take his course, is spending a few months in my office. He does not know what he is going to do yet. Will he be debarred ?

Mr. Baker : I think there should be the greatest freedom possible in this matter in its early stages. A trial should be given, but it should be understood that students should be registered.

Mr. Wickson : According to our by-laws can we register a student who does not take the examinations ? Mr. Baker's idea seems to be that, suppose there is a draughtsmen's club or something of this kind formed, it is not permissible for a student to come and take advantage of the studio work because he is a member of that club without joining the Association.

Mr. Langton : Remember, these classes are free. To register costs six dollars. Any student might well pay the six dollars merely to get the advantage of these classes.

Mr. Burke : I think that would be satisfactory.

Mr. Baker : That would also apply to students in the offices of men who are not members of the Association.

Mr. Wickson : Mr. Langton, is it the case that no student can register unless he is articled to a member of the Association ?

Mr. Langton : It is put in another way that students of the Association must be articled for so many years to a member of the Association.

The President : It comes to the same thing.

Mr. Wickson had here to leave the convention, and Mr. Burke took the chair.

Mr. Langton : Mr. Chairman, it has just been pointed out to me by Mr. Munro, that students cannot get into the Association, although there is a by-law that students must be registered. It is just as well that students should have to pay an examination fee to join these classes.

Mr. Burke : I think it is a good idea. Mr. Baker asked if the Committee had made any plans regarding the starting of the studio work. We have not made any plans at all. We simply discussed the men for patrons. I do not know what we can say about the commencement. I daresay the proper thing would be to get the patrons together and see what they will do about starting their work.

Mr. Langton : I should like to bring forward some other business. The proposal that I wish to make is that the Council be instructed to take some step to memorialise the Government to have some Dominion buildings designed by architects in private practice, instead of all by government architects. Mr. Fuller the government architect died some time ago and since his death no chief architect has been appointed. Mr. Fuller was singularly fitted for the position, and it will be very difficult to find a man who will fill his place. It is a question whether in any case public buildings would not be better designed by private architects. The difficulties in the way of a chief architect as a designer appear to be greater than those in private practice. In the United States the plan I am proposing has been, after long advocacy by the profession, adopted, and the general opinion of its success as a method is the principal ground of confidence I have in bringing forward this proposed. It seems to be agreed that when the general architectural practice has reached a certain pitch of excellence there is no longer need for a government architect and indeed the advantage in favour of design is with the private practitioner. I think practice in Canada has reached the point when the transference of public designing from official to private hands should be considered. There is another reason why public buildings should come into the field of private practice, speaking of course from the point of view of the public good, and that is that there are always a certain number of monumental buildings being distributed to the profession which may be regarded as prizes to be aimed at and will have a material effect in elevating the aim of the profession and raising the standard of architecture. I move that the Council be instructed to memorialize the government on this question. A Chief Architect is just as likely to be appointed for political reasons ; while when he is appointed he is appointed for life ; there is not the same opportunity for repentance that there is in the case of the appointment of a private firm for one building at a time.

Mr. Burke : Do you consent to have the motion refer to the Ontario Government as well ?

Mr. Langton : Certainly ; and Canadian architects specified as well.

Mr. Gordon : While you are at that line, I think you should refer to Government employees engaging in private practice. I would move that the Council memorialize the Ontario Government in regard to this practice.

Mr. W. R. Gregg : I think that has already been passed upon by the Government. A Government employee is not allowed to use the public office or telephone for his own work. We have got all we could get from the Government. Why should we try them again ?

Mr. Gordon : Because there is a great deal to be gotten yet, and why should we not persist ? It is only by emphasizing the thing over and over again that it can be obtained. The Government can only be educated through the influence of the public. It is a thing that is comparatively small, but it will grow. It grew very rapidly in Ottawa, and it was only stopped in Ottawa by bringing pressure to bear upon the members in the Ottawa Government. And we have to take some steps.

Mr. W. R. Gregg : I think we should find out what the Council has done in the past, and if the Council has conferred with the Government in the past and got its answer, and still there is trouble, we should deal with individual cases.

Mr. A. H. Gregg : It seems to me that this is a kind of small, trades union sort of business. I don't see what we have to do with what men do outside of their office hours.

Mr. Symons : We might bring that to ourselves, Mr. President. The question of allowing a draughtsman to carry on work of his own is similar.

Mr. Gray : I second the motion. I think that Mr. Gordon's motion is along right lines. I also agree with Mr. Symons as to bringing this matter down to our own employees.

Mr. Langton : It is, I suppose, not our place as architects to interfere in this matter more than any others of the public, except in so far as it affects our practice. I should personally feel very slow about doing anything that was aimed particularly at improving our own practice, and I think that if it went in with the other memorial which it has been proposed to send in to the Ontario Government as well as to the Dominion Government, it might give the latter the appearance of having a motive that we do not intend. We ought to let this stand as it is, as a public spirited effort.

Mr. Baker : I would move, sir, an amendment, that while the convention approves of the principle of Mr. Gordon's motion, it take no action on it.

Mr. Gordon : I think it should be decided whether the motion is wise. If that is the case I am quite ready to amend my motion, that we approve of the principle that it is wrong for the government employees to engage in improper practice, and that at the proper time it be placed before the government. The case I have in view now is one of a building costing over a quarter of a million dollars, which has been put up by one government employee—which I think is not a very small amount, it is a very large thing. If the regular commission were charged there would not be any objection, but in cases of this kind these men, because they have no expenses, do the thing for a very meagre amount, and it has a bad influence on the whole profession, and that is what I am aiming at rather than preventing a civil servant getting a little business which might come to some of our offices. It is that aspect which appeals more strongly to me. I would amend my motion that we approve the principle that it is wrong for a government employee to engage in private practice.

Mr. Baker : I beg to withdraw my amendment in that case.

Mr. Burke : With the consent of the seconder we will amend Mr. Gordon's motion. (Carried). Is there any other business ?

Mr. Baker : Mr. Chairman, we should have a report from the Rooms Committee, and also from the Proceedings Committee.

Mr. Aylsworth : As Chairman of the Proceedings Committee I might say that the committee had one meeting since our last report, the only business being some preparation for printing the annual proceedings of the Association, another being called for next Friday evening.

Mr. W. R. Gregg: Before Mr. Wright reads his paper let me make one or two announcements. I don't think it is known to all the members in the city and those outside that the library books are sent to outside members. Any library book will be sent post paid to any outside member, if he sends a post-card for it, if he keeps it the specified time and sends it back at his own expense. The hardware merchant supplied fifty keys for the rooms, and any member desiring to buya key for 25 cents will have access to the rooms day or evening. I want to make an apology in connection with our agenda. I omitted Mr. Baker's title, A.R.I.B.A. I find that I may have had some excuse for this, as according to the last report of the proceedings of the Royal Institute, he has been received as a Fellow of the Institute, and the title Associate would not have been correct.

Mr. Wright then read a paper on "Design in Modern Architecture," which was received with hearty applause.

DESIGN IN MODERN ARCHITECTURE.

My excuse for taking up this subject at the present time, if any excuse is necessary, is the remark made frequently from the platform and through the press, that we are without any architecture, and that everything of to-day is copied. It is also a subject which I believe will provoke discussion and prove useful on that account.

In part then the object of this paper is to bring forth of itself and by discussion ideas which shall not only be profitable to us as members of this Association, but may also cause the general public to think somewhat differently of our work.

First, then, let me state a number of points, which you are all familiar with, but which under the circumstances will bear repetition.

All building is not architecthre, any more than all writing or language is literature, and it is quite as logical to condemn this latter art because there is so much trash printed, as to condemn architecture because the greater majority of the buildings on King street do not display any art. The same may be said of any of the arts, and yet these carping critics will in the face of all that is bad admit that we have modern gems of music, of painting, of sculpture, and of literature, and admit further that they may have to travel to hear and see them. But because they cannot from their own windows view the beauties of architecture everywhere, they raise the cry that all types of buildings of to-day are copies and that the two characteristics of modern architecture are. 1st, variety of style, and 2nd, lack of originality. Many aspiring architects have evidently this same deplorable view, for I have been requested on many an occasion to name a good book of architectural recipes. The demand is for something new, some new architectural invention. They say when looking at buildings where the openings are spanned by beams, i.e. are rectangular, why that is Classic, if round, that is Romanesque; if pointed that is Gothic, etc.

If then the openings in our modern work, in order to satisfy their desire for inventions, cannot assume any of these shapes we are limited to no openings, no entrance, no exit, no admission of light, etc. What do these people expect? Is is not safe to say that this is but an illustration of the old proverb, "a little knowledge, etc.," or rather, perhaps, a want of consideration on their part. Would not many of these same people give favorable descriptions of many of our modern buildings? Would not most of them find fault with many features of much if not all of the early work? I certainly think that we would get from them as favorable a criticism of a modern building that we might name as of any one building of the early periods chosen by themselves, and for that matter of any dozen or hundred buildings. Again it might be pointed out that we have records of but very few of the buildings of these early periods.

Let us stop this form of discussion and ask ourselves what are we doing and why are we not doing otherwise. We are not living in an age where the church, the state or the monarch (in any form) is all powerful, and can on that account divert unlimited wealth or resources in the line of architecture thus resulting in the erection of cathedrals, temples, palaces or castles. But on the contrary we are living in a commercial age—a period in which our art productions in architecture must be considered as investments and reduced to profit and loss in cold coinage.

Our admiration for a building to-day (and we have such admiration for many) depends upon the thought expressed in it, or, in other words, upon the thought expended in its design, and the greater the power of the mind of the architect who has created or developed the design, the deeper the thought expressed, and consequently the greater the lasting qualities in the beauty of the creation.

In the first place he must produce a plan that is perfectly suitable for the work intended. This may require a knowledge of the business and business methods of any of our commercial enterprises whose success in this economical age depends upon an almost innumerable number of small arrangements—or conveniences—or facilities for the transaction of such business, knowledge which the architect must obtain by experience not only of himself but from close and careful study, as well as from all the different clients for whom he has done or is doing work. Not only must he provide for this present service, but also for a growth of the enterprise, the rapidity of which is entirely problematical. Thus when an entrance is or may become necessary he provides for one—where light is necessary he admits it boldly, and where light is not wanted he leaves the wall surface whole. The result of this thought is an expression on the exterior, on the facades, of the interior requirements of the business, or of the purpose for which the building was erected. The building may from its exterior appearance alone declare it to be an armoury, a school, a court house, a church, etc. This classification is, however, very superficial, but the more masterly the subject has been treated the more minute does the classification become and the greater the range of thought expressed. But with this, as with any other art, the refinement in the production requires an equal refinement in the observer in order to be appreciated. In architecture we cannot hope to proceed much faster than we can educate the public to appreciate. It is therefore with feelings of regret that I read in the CANADIAN ARCHITECT AND BUILDER of December the following: "The Toronto Industrial Exhibition Association have sent out a circular inviting architects to submit competitive designs for a new main building and several subsidiary buildings. The cost of the main building is estimated at $106,000, and of the lesser buildings from $5,000 to $15,000 each. To the author of the accepted design for the main building a prize of $250 is offered, and to the author of the accepted designs for the smaller buildings prizes of $40 and $50. Architects are required to submit plans, elevations, perspective and brief specifications."

This sounds like throwing a morsel to a pack of hungry wolves.

Have the Industrial Association stopped to think over the above offer, or have they been led to believe in some manner that the above course was all that was necessary? Have these men, who are supposed to be shrewd business men, considered how long they might expect to employ the services of one respectable set of brains for the chances of the prize offered, viz., $250? Have they thought of the mere labor involved in the production of plans, elevations, perspective and brief specifications?

There is one ray of light however which should be encouraged, and that is their handing the appointment of judges over to the Ontario Association of Architects. For the sake of themselves, for the sake of the city, and for architecture generally it is a great pity that in making the provisions for the competition they did not also take the opinion of the O.A.A., which in matters of this kind is undoubtedly the best authority in Ontario.

Returning to our subject we find that another reason for the beauty in design lies in the careful study of the proportions of the various parts. These proportions cannot be set down in a column like the multiplication table; they are not mathematical but artistic, and are so interdependent that every problem must be studied by itself and the proportions adopted must be such as to give a proper scale and produce a harmony of the whole, a harmony which can only be made complete by a careful arrangement or grouping of these various parts.

In addition to all this, the material out of which the building is to be erected must receive careful consideration. We have on account of the long continued use of brick and stone masonry become accustomed to thick walls, to deep reveals at the windows and doors. And the time was when this was a necessity, the eye required it. This however is passing if not already passed. Steel is in such common use to-day that the mind is fully convinced of the stability of the thin wall, of the narrow reveal. Does it not see in the brick or terra cotta a thin fire-proofing shell? Does it not appreciate that within this shell lies the bone and sinew, the strength of the building in the form of steel construction? Again, good architecture of to-day is often spoiled by its surroundings, due to our economical ideas; land is too valuable, and occasionally to lack of thought or design, incongruous objects called buildings are crowded around what would otherwise have given delight. Observe the cathedrals of England how beautifully they nestle among the trees or rear their spires heavenward from the lowlands or again how imposing and boldly they stand on the tops of elevations of more hilly ground. On the other hand the cathedrals of France command attention because of their proportions, they dwarf their surroundings into insignificance.

The success of the building scheme of the World's Fair at Chicago was largely due, if not entirely so, to the design of the whole in harmony.

These were Classical buildings, but could they have been copied from a book? Were they mere copies? Certainly not, but rather did they display wonderful thought, power of design (inventive power if you will). The Classical idea and the harmony might have been attained if all of the buildings had been erected from the one design (copied from the one page of Classical reciepts). But their beauty was won because of their fitness for their work, because of the thought expressed in the design of each, because of the harmony in the design of the whole, and last, but by no means least, by the design of their surroundings. These latter were as carefully planned, studied and executed as were the buildings themselves. The extent and form of the grassy lawn, the water ponds with their alder banks, their reflections of the blue heavens and marble buildings, even to the ducks swimming on the surface, all was studied to produce an effect which displayed forethought and power of design that has seldom if ever been excelled, and which won from all sides the loudest of praise. Why is it that after this example so near home our Industrial Association did not profit by the lesson? Perhaps it is because the scheme at Chicago was so large. This, however, is no reason why we should not work in a modest way, but ever in the right direction. I have no right to speak except as an individual member of this Association, but I feel sure that we are willing to lend this or any other organization a hand with suggestions as to methods which will produce the best architectural results.

I have spoken of buildings as expressing thought and design when the ideas used may have been derived from a variety of sources, a statement which perhaps would be the better of an illustration. An individual may be a good mathematician and display thought even though he is using the fundamental rules of arithmetic or the laws of Newton. An artist may display thought though working with a simple palette he paints the same sky, sea and landscape as have been painted for centuries and yet their productions are classed as works of art, even though copied from such a universal book of art receipts. In the same manner an architect may design a building and display thought, etc., using ideas derived from the past.

Why do we admire the main building of the University of Toronto? Why is it that after passing that building day after day, year after year, we still admire it? Because it is more than a mere copy, more than a mere page out of our receipt book of Norman architecture. Is it not because it is a design, because it displays thought? It is a work of art and a lasting monument to one of our number who has gone to his rest. Here we have in the midst of our busy city a secluded quiet spot and in its centre stands a building, which seems to say to the noisy rabble and buzz of traffic—keep still! stand off! quietness is what is required for university life. As we stand viewing the building, resting on its grassy terrace from across the wide lawn, we observe its restfulness, grace and dignity. The entrance is well marked and inviting. Look at it where you will and the repellant and military feeling of the old Norman work have disappeared and in their places stand the thought, the design of the architect.

Look at the variety of the work, so varied in fact that every day seems to reveal something new. Observe the grouping of the windows how they mark the large halls, the smaller subdivisions of classrooms, etc. Now look at the round feature at the extreme west and see how well suited it is for the protection of valuable apparatus. The whole building unites to form a group, a unit of design, a picture which is indelibly stamped on the heart of every graduate as well as producing a lasting impression on every visitor too ur fair city of Toronto.

Mr. Paull: Mr. Wright's paper contains many valuable points. He names the University of Toronto as being a building which would attract our attention and bring forth our admiration. The University of Toronto has one advantage which other buildings in Toronto have not. It is in a position of isolation. Its beautiful form has plenty of room to show itself, and you can go and view the perspective of it from many points, and at every point you can see some new beauty. It is a great pity in my opinion that there are a great number of very fine buildings in Toronto lacking those conditions, and if there were more room surrounding them they would look very much better. Very many buildings built by the architects of the city of Toronto are cramped up and cannot be seen to advantage. For instance the Sick Children's Hospital, on College street, a fine building, but not having room enough to be seen to advantage. Now suppose that $100,000 was the cost of that building, and suppose that $20,000 were expended in taking down the buildings around it so that the building could be seen to advantage, would it not add very considerably to the advantage of the building and to the utility of the work, and create as it were an importance to the city of Toronto itself? Many other buildings might be mentioned that are so situated. Even our own City Hall has not sufficient ground around it to see it to advantage. If you go to Buffalo you will see that their City Hall is well arranged as to site and has plenty of ground around it.

Mr. Aylsworth: In regard to the Exhibition Building Competition, it strikes me as strange that this Association in some way had not been consulted by the managers before issuing the advertisement. It seems that the Association is not well known to the citizens. I don't know if there is any way that it could be made better known, but that is an instance showing the necessity for it. It seems to me that the members of the Association ought to have been more in touch with the Exhibition managers. It might be worth our while to appoint a committee to look after that sort of thing. If we had had such a committee something else could have been done. Perhaps it might be thought worth while yet to appoint one. The Exhibition Board I don't think should be permitted to go on and disfigure the city; they represent the city in some way, and the citizens should have some hold on them, and the architects should be sufficiently strong to guide the citizens. Just what shape that might take I cannot say. It seems strange that such a large number of architects should not have sufficient influence to have some weight with all such corporations.

Mr. Burke: Perhaps Mr. Aylsworth is not aware that the President called together some others of the Association, among whom were Mr. Eden Smith and myself, who went down and saw the officials of the association. I was not able to remain for the interview, but I understand that about all that could be accomplished was to gain consent to appoint experts to be selected from the Association membership. While Mr. Wright was reading his paper, I could not help noticing how the Americans went about the inauguration of their exhibition, putting it into the hands of competent architects and landscape architects. I do not know whether it is too late now to do anything towards guiding the Exhibition management into proper line.

Mr. A. H. Gregg: There are two instances brought before the Association, the Exhibition and the University buildings, where there has been a number of buildings erected one after the other. At the University the library was built in a splendid position, but with that exception hardly any of the other buildings have been placed with any regard to artistic grouping, and the Exhibition buildings have been managed in the same way. When our University was burned down, some landscape gardener might have laid out the grounds and allowed for coming buildings, and much better results would have surely been obtained.

Mr. Baker: Mr. Wright has referred in the early part of his paper to the difficulty of obtaining originality in our designs and the great danger and tendency there is towards plagiarism. I think if we look over the buildings of the United States it will appear to us that there is very little original work; that most of the large buildings have been designed along the lines of magnificent examples of architecture which have been erected in earlier periods. Are we in Canada really wise to attempt the original, or would we do better to adapt what we know to be good? It is a question which has been before us at all times, but is difficult to decide. Take the architects in the United States, and of course we have to turn to them, as they have always so much work at their disposal. Those who have tried to work along original lines have not succeeded; they have given it up and gone back to precedent. For example, some of the finest buildings recently erected in the United States are admittedly adapted from important European examples—Madison Square Garden Tower in New York, the library at Boston, the New York Herald building, and many others. I mention these without hesitation as they have even been published side by side with the Eurpean examples in a comparative way. I think architects should work together when designing and erecting adjoining or even adjacent buildings of all kinds. Petty jealousies often prevent good architectural effect. Last night we had a view of several New York buildings. I noticed in passing over the view one building which was perhaps an eighteen story building erected beside a twelve story building; evidently the taller building had been erected since the other, but the cornice line on the smaller building had been carried artfully around the taller building improving the appearance of both. Many examples could be named proving the advantage of consultation in the public interest, and I hope the influence of our Association will improve matters in this direction. With regard to the Exhibition we must not forget the state of architectural embryo the whole of it is in. The fact that Mr. Wickson and other members of the Association were asked to confer with the association and succeeded in having the conditions made as nearly satisfactory as possible should not be overlooked. It is true that the prizes are very small and look as Mr. Wright said, like "a bone thrown to a pack of wolves." But Mr. Wickson if he were here would explain to you that he admitted a certain amount of reason in this. It was thought the architects of the city of Toronto would be patriotic enough to enter into the competition and help on the city's welfare. It is true that designs are asked for individual buildings without any regard to the placing or grouping of them, and it is evident from this that the Exhibition Association has overlooked this, from an architectural standpoint, vital point. All of us who have given the subject any thought will realize what a splendid opportunity there is of grouping the buildings, spaces and courts, and even of introduc-

ing the delightful element so desirable at exhibitions, water, the vast stretches of which through the Chicago Fair gave the White City the delightful transparency and lightness, and the absence of which with the absence of music was the cause of the heavy, serious business-like appearance of the marvellous exposition recently held in Paris. Consequently I think it is to be regretted that this matter was not considered from that point of view. The large sum of money which it is proposed the citizens should expend there, ought to be well expended indeed if the placing of the buildings be properly handled.

Mr. Baker moved a vote of thanks to Mr. Wright which was seconded by Mr. Belcher and carried.

Mr. Aylsworth: It is clear to us all as Mr. Baker says that a splendid opportunity still exists for a thorough replanning of our exhibition grounds; not that great changes need be carried out at any one time, but that when money is to be expended whatever is done may be as part of a complete whole to be realized in the course of time. There is no body of men more competent to outline such a scheme than this Association; but in this business age something more than planning must be done. We must not only have an artistic and feasible arrangement to present, but it must be so placed before the executive body that there shall be no chance left open for its rejection. As our time is now perhaps too limited to fully handle the problem I propose that it be made the principal subject at our monthly meetings during the balance of this winter, first to develop such a scheme as the citizens cannot but be proud of, and then appoint such a strong and permanent committee to see it gradually worked out that the City Council Exhibition Association can never shake them off.

Mr. Wright: As the grouping of the University buildings has been referred to I should like to ask Mr. Dick what opportunities have been offered him in this respect. A difficulty in the way of a comprehensive scheme is the fact that there is continual progress in the aims of the University, and ideas which were accepted a few years ago are now in the process of change.

Mr. Dick: Regarding the University buildings a particular building was proposed and a particular site selected for it, and of course one would have liked to have carried out all the buildings in the same style as the University itself, but unfortunately this is a very expensive style, and the library is the only one that could be made to harmonise with the main building. It would have been a very excellent thing to have had a landscape gardener to lay out the whole buildings, but as Mr. Wright has pointed out, ideas have changed so considerably, that the ideas would have had to be modified as the buildings were erected.

Mr. Gordon: It might be interesting to note that the public are gradually getting educated on this question of grouping of buildings. The process is slow, but the college authorities are beginning to realise that the general effect of their buildings depends so largely upon their grouping, and I might mention that last summer I was asked to go to Kingston with just that object in view, to give an opinion as to what would be the best method of grouping the buildings, in view of the lack of effect from the McGill buildings, and to some extent the lack of effect of the Toronto buildings. The authorities recognized that although they were doing things in a modest way they might be planned ahead to get the best grouping of buildings, and that the whole would have the best possible effect, and it is a pleasure to see that college authorities are beginning to realise the importance of grouping.

Mr. Burke: Would it not be well to memoralise the Toronto Exhibition Association, and point out the pains the Pan American Exhibition people have gone to in the grouping of buildings, landscape architecture, etc.

Mr. Hall: You would have to send it to the city, Mr. Burke.

Mr. Burke: To the proper authorities, also give it to the papers, so that the public would see what was suggested.

Mr. Gray: I think Mr. President that would be a good idea. The existence of the Association is kept too much from the general public. There have in the past been cases right in our midst where the Association has been looked for by the public. Recently with regard to the St. Lawrence market buildings the public have looked round about aud said "Where is your Association, what are you doing?" "Where is the Ontario Association of Architects?" I think that the Association has been asleep during this last year and has lost opportunities and kept in the background when it could have been doing useful work. I feel that it is too bad that the public should have to look round about for the Association when these things occur. When this exhibition matter was brought up, too, we find the public asking "where are the Ontario Association of Architects, what are they doing?" and we have simply to shut our mouths.

Mr. Baker: Well, somebody ought to get up pretty quick. I would like to ask this Convention whether it was the Association or Mr. Gray that was asleep during the past year. Nearly every morning when I look at the paper, I see that the Association of Architects has done so and so. Certainly 10 or 20 times during the last year I have noticed this. We cannot hang a banner across the street from the doorway down stairs stating that the Association is to be found here. I would rather that the recent Kingston University competition were discussed than the exhibition. Perhaps, after all, the worst we can say about this exhibition competition is the prizes offered. If they do not see fit to offer a larger premium, we can appreciate that it is because they are tied up in every direction. Regarding the Kingston College buildings: Anything which has ever been placed before a body of professional men which would equal that in absolute lack of knowledge of decency in the procedure of engaging professional assistance, I do not think I have ever seen. If any action is to be taken to-day, I think it ought to be taken against that kind of competition. I think several of our members felt this very keenly. This is an instance demanding an explanation, but in the other I think we should rather do what we can to show our appreciation of what they have tried to do for us.

Mr. Gray: With all due respect to Mr. Baker's reference to the publicity of the Association in the daily papers, the Association is not known as it should be to the general public. Now I do not care what Mr. Baker says, it is a fact that the Association is not known as it should be to-day.

Mr. Baker: How should it be made known?

Mr. Gray: I think one of the methods is in using it in our own daily experience; using it from time to time; let the people know about it. I maintain with all due respect to Mr. Baker that it has not been brought sufficiently before the eyes of the public.

Mr. Aylsworth: Mr. President, I am glad to see a little discussion on the lines I intended to evoke, and I do not think this might be confined to exhibition or university matters. It seems to me that we might prepare for the press a little more extended notice of this Convention than has been done heretofore, and announce that a standing committee had been appointed, so that the public might know that the Association is prepared to consult with any such bodies at any time in future.

Mr. Gray: Allow me to give you an idea of that matter which I spoke of. When the St. Lawrence Market was brought before the Board, that Board turned round and stated that they did not really know of an Association such as the Ontario Association of Architects.

Mr. Gemmell: I don't know whether this discussion is on Mr. Wright's paper or not. The only suggestion which I see that would arise out of Mr. Wright's paper (laughter)—excuse me saying only, but I mean the only PRACTICAL one would be: I think that a proposed competition that the Exhibition could bring forward would be for a landscape garden plan, comprising the whole laying out and construction of the Exhibition, when, if they wanted to erect a new building, it could be laid down in a position making it a fitting part of a well digested plan to utilize the ideal site that would not ignore the effects to be got from that beautiful stretch of water, Humber Bay. I therefore think that what the exhibition wants most is a scheme for a whole. Their buildings now are not expensive. They should not be considered as opposing one grand scheme at all. They could be torn down or removed. Perhaps the Association would move in this direction of bringing forth a competition for laying out a scheme for the whole Exhibition, if properly brought before them.

Mr. Langton: I am always opposed to puffing the Association simply for the sake of puffing it. As a matter of fact the Association has been very weak for a few years for lack of support, but it has not been idle in matters where it could help the city. We have drawn up a complete and perfect set of building by-laws (which were ignored), intervened in the case of the Market Buildings, and have done everything we could do. If the City Council did not know of the Association it is certainly strange, especially in connection with the market competition, for both the Mayor and the City Engineer received letters upon the subject and had an opportunity of perusing a copy of our conditions of competition. On a certain occasion in the days of the old Guild—of blessed memory (laughter), we had a meeting over laying out the old Upper Canada Grounds, and had several schemes for laying them out. Why could not some of the monthly meetings be devoted to laying out the Exhibition Buildings in the grand style; and Mr. Wickson has already denoted to the Association that the city is willing to do something in the direction of assisting the Association in carrying out the buildings.

WEDNESDAY AFTERNOON SESSION.

The convention having re-assembled, Dr. P. H. Bryce, Provincial Health Officer, presented his paper on "Problems in Maintenance of Purity, Equability and Moisture of House Air."

PROBLEMS IN MAINTENANCE OF PURITY, EQUABILITY AND MOISTURE OF HOUSE AIR.

GENTLEMEN:—It was with some diffidence that I complied with the request of your Committee to read a paper before a society composed of gentlemen who are daily engaged in dealing with the practical details of house building, and I must appeal to your indulgence if in my remarks I betray an ignorance of practical details which are to you but the alphabet of your work. My excuse for attempting a paper at all has been due, however, to a conviction growing out of my observation, that we are, in matters of ventilation and heating, not living up to our knowledge. For instance, last summer the Ladies' Committee were arranging for the heating of a mission church, and I asked them what arrangements for ventilation were included with the furnace. They answered that they did not know, but supposed that the furnace dealer would see to everything. However, I was asked to find out, and learned from one of our prominent makers that no provision for fresh air was in the proposed tender, and that it was intended to draw the air off at the floor back to the heating chamber around the furnace. When I protested that surely they were not going to make the people rebreathe the air, I was told that not one furnace in five in the city nowadays provided for anything else. If such be the case, and if the term "economy" is to be applied to furnace heating performed after this fashion, then, indeed, it would seem high time that architects and sanitary officers place this matter in its true light before the public, and insist on the application of the true remedy.

The problem of how to heat economically and yet efficiently has been, and is, both a complicated and difficult one, owing to the many circumstances of latitude, exposure, nature of employment of inmates, number of occupants of dwelling, and so on, and yet there are some primary principles which must be fully understood if even a moderate degree of success is to be attained. I shall attempt to outline these in order of importance as they appeal to me.

Owing to the constant atmospheric movements of external air it must be remembered that the external air is, even in cities, infinitely purer than the best house air under ordinary conditions. For instance, Dr. Paul Regnard quotes a table from Miquel giving the bacteria per cubic metre in air as follows:

Air over the Atlantic	0.6
Air of Paris at summit of Pantheon	290
" " in Rue de Rivoli	3,480
" " in a new house	4,500
" " in the sewers	6,000
" " in an old house	36,000
" " in the hospital de la Pitie	79,000

Or as Regnard says, a patient in La Pitie inhales 790,000 bacteria daily.

As regards chemical constituents, Dr. Angus Smith, Saussiure, Muntz, and others, have found that the carbonic acid of the purest and most impure outer air does not vary more than between 2 and 4 parts in 10,000, whether on mountain top or in the slums of great cities. To illustrate further, Pasteur and Tyndall both found that sterilized solutions of beef bouillon, could not be exposed a moment in a room without danger of infection by some floating microbe, while on the mountains outer air was practically sterile. Clearly, then, our problem involves the introduction into houses or living rooms of a reasonable amount of outer air, if we believe that fresh air is necessary to health. Now it is quite apparent that we are at once contronted with the question of how to do it, and how to pay for it. After much consideration, I am convinced that it is possible, with reasonable economy, to keep house air fresh, but only by an appreciation of the several physical laws entering into the problem.

First, the construction of a warm building—this is our first point. But some one says, here again it is a matter of cost. Partly so, and only partly so. Practically we have three building materials, stone, brick and wood. Speaking of refrigerating machines, Leask remarks, that a large percentage of the actual work done is required to make up for the transfer of heat through the walls, floors and ceilings, occasioned by poor insulation, which amount may be measured experimentally. Tables are given as illustrating the varying conducting powers of substances. Prof. Shaw, of Cambridge, indeed gives a formula for estimating the amount of heat lost in one hour by conduction through an area of one foot square of different substances of one inch in thickness, with a difference on the two sides of from one per cent. upwards.

Copper conduits	3225.0 units.	Cork	0.90 units
Iron	477.0 "	Water	5.82 "
Stone	17.0 "	Air	0.16 "
Brick	4.3 "	Glass	6.66 "
Oak (across fibre)	1.70 "	Slag wool	0.314 "
Brick dust	1.00 "	Asbestos	same as above
Coke	0.99 "	Paper	0.20 "

It is thus apparent that enormous differences exist in the conducting powers of our several building materials, and that very important facts regarding the conducting powers of other substances may become of practical service to us under many circumstances. Thus, Leask gives several examples, of which the following illustrates the successful arrangement for a refrigerator wall.

Outer wall, 14" of brick.
Next inner wall, 4" of pitch and ashes.
Next inner wall, 4" of brick.
Next inner wall, 4" of air space.
Next inner wall, 14" of brick.

But assuming that we are to build an ordinary 14" wall, we must see that two points are well attended to (a) that the mortar is laid so that the wall is not a seive, and (b) that its inner surface is grouted, and a good stripping is laid on tar paper, with an air space between this and the plaster, and thereby get at least some of the non-conducting conditions we are seeking.

But the question will be asked, what difference can the wall make if the air is to be frequently changed? An example will probably best illustrate the case. Assume a room with two outer walls of 30 ft. each by 16 ft. in height, and one ft. in thickness. This represents 900 square ft. of external radiating surface. Assume that one inch thick with one degree of difference between outer and inner air means in heat a loss of 4 heat units, one-twelfth of this is lost with a foot in thickness, or 300 heat units per hour. Let the difference in temperature be between 69° Fahr. and zero, and not only will there be a loss of sixty times as many units of heat, but the rate of loss of heat is directly proportional in rapidity to the difference between the internal and external temperature. But assuming that this most important matter of making a building warm, compatible with moderate first cost, is accomplished, we have still the problem of its heating. It is apparent that houses, essentially dwellings, must most concern us. Warehouses and similar large buildings, are usually filled with goods rather than people, but schools, workrooms and factories, as well as dwellings, must claim our attention.

It has always appeared to me that the large buildings with many inmates is our simplest problem, since the means applied may be mechanical and caretakers may be provided to supervise such. But I think it will be common experience when I say that the idea of introducing adequate air while installing our heating apparatus has hitherto been given relatively but little thought.

Take the heating of a school or church, for instance, and we have hot air furnaces, steam and hot water, to choose from. Suppose it be a hot air furnace which is chosen. Air is introduced into a school room at from 100 to 150° Fahrenheit at a single point, with its moisture reduced by expansion of the air to perhaps ten per cent. or less of relative humidity. It is delivered at one point often creating a draught, and a chimney register of a few square inches area is usually the only exit. Analysis shows the carbonic acid relatively in excess. Windows, if open, again subject the inmates to the danger from draught, and so are only occasionally opened. If the heating be steam we have heat alternately in excess and defect, while the likelihood of getting a fair amount of moisture into the room, and a fair degree of purity, is seemingly very slight. In the case of hot water heating, we have in the regulation of the degree of heat in the rooms many advantages, but in the matter of air purity the same problem of how to maintain a reasonable purity of air is quite as prominent as in the case of steam. In both cases it is not uncommon to have fireplaces in rooms, and in such instances a fair degree of purity is naturally maintained by the chimney shaft, greatly increased, of course, if a fire is kept in the grate, although the air near the floor is relatively cold in consequence of the draught from beneath doors leading to cold halls and the outer atmosphere.

The question, therefore, before us is: Can we, with the ordinary means at our command, improve the air conditions in the living rooms of public or private dwellings without an increased expense? I believe that we can, and I propose to deal with some of the methods and explain the reasons for my opinion.

Suppose that we have to deal with an ordinary school building. What methods should we pursue to effect the desired end? I shall assume that the walls have been made in a large degree non-conducting. In a school building of four rooms, each providing for

fifty pupils, and giving 240 cubic feet, or 4x4x15 feet to each, it is found that 2,000 cubic feet per pupil per hour will keep the carbonic acid at 6 parts per 10,000. In order to supply this, 100,000 cubic feet of air per hour must be passed into each room, whose cubic capacity is 12,000 feet. This means 8⅓ changes per hour. To supply this an inlet shaft 2x2½ feet is required, which delivers air at 6.94 feet per second. It is found that air coming into the room at this rate, at a point above the head, say 7 feet from the floor, with the mouth of the delivery duct at an angle of 45 degrees, will cause the air to distribute rapidly laterally, while the vis a tergo, or head, and the temperature at say 80 degrees Fahr. will cause the air to rise and be propelled across the room, where reaching outer walls it will be cooled and will descend and return at a rate not exceeding 2 feet per second along the floor towards an exit shaft, which should be at the floor near the inlet. To favor even distribution the windows should be double and the walls non-conducting as far as practicable. In order that this work be done, the air must be previously warmed, in the cold air room of the basement, and forced into the shaft by a fan or drawn in by heated extract shaft. The method provides a very important means of supplying outer air as it is warmed, with an opportunity of receiving moisture in the cold air room from broad and shallow evaporating pans supplied with water automatically by a ball-float and valve. To illustrate the importance of this point, some figures may be given. It will be remembered that as air expands with heat, its capacity for moisture increases. The percentages of moisture at different temperatures have been calculated. Thus at

0°	Fahrenheit	= Moisture	= 0.09 per cent.
32°	"	= "	= 0.37 of 1 per cent.
42°	"	= "	= 0.56
52°	"	= "	= 0.81
62°	"	= "	= 1.17
72°	"	= "	= 1.68
82°	"	= "	= 2.36
92°	"	= "	= 3.28
102°	"	= "	= 4.54

Thus the relative humidity of air more than doubles with every twenty degrees, proportionately increasing with increasing temperature. Now, it will be further noted that air in motion practically never becomes saturated as it passes over moist surfaces, but takes up probably 75 per cent of saturation. Hence, outer air at 0 degrees going into a room, we shall say, at 90 degrees, will at 75 per cent of saturation have taken up ten grains of vapor, or it will hold thirty times as much moisture as that in outer air at zero. In other words, the 100,000 cubic feet of air hourly introduced into a school room should be supplied with 1,000,000 grains of water, as vapor, or it would actually take up through evaporation 13 gallons of water hourly. As however, the moisture from the breath of children yields a very notable amount of moisture, we may say ten gallons of water ought to be provided hourly. This amount seems enormous, and would seem to actually use up heat. But the heat is never lost, it is only latent, and the service rendered by the moisture is apparent. If the air goes into the room too dry, and I am informed by Mr. Stupart of the observatory, the air of the house heated by an ordinary hot air furnace, has a relative humidity of not more than 25 to 35 per cent even with a good evaporating pot, it is apparent that the air must, from every available source in the schoolroom, seek its moisture. This it gets from walls and furniture, but especially from the mucous membrane and skin of pupils. Now assume that this 100,000 feet of dry air becomes even partially saturated, and I have found it in a school room heated with Smead Dowd furnace, at 50 per cent of saturation, it is apparen that it will in an hour have removed a large amount of moisture from the bodies of the pupils. But to evaporate one pound of water requires nearly 1,000 units of heat, and hence it is apparent that even if two pounds of water were given off by the breath and bodies of fifty pupils per hour, 2,000 heat units would be utilized. But very much more is lost by insensible perspiration. Now the practical point is this, that since the body temperature is 98.4 degrees F., it is apparent that the air of a room does not warm the body, but only prevents the loss of heat aided by clothing, with too great rapidity and as evaporation produces cold, the lower the air is the more rapid the loss of heat by evaporation, and hence the constant experience that in rooms with dry air a temperature of 70 to 75 degrees is required to prevent a sensation of cold, whereas if the air held more vapor much less loss of heat would take place by evaporation and the sensation of cold at 60 degrees F. would not be as great as in the other case at 70 or 75 degrees. Indeed, we all know that in English text books a temperature of 60 degrees F. with the common fire-places of that country is set down as a normal house temperature, due to the moist air constantly brought into the room by the draft. I have dwelt upon this point at some length, because I am convinced that more injury is being caused by the abnormally dry atmosphere of our houses than from any other cause.

This matter of reducing the temperature of a living room further bears a very important influence upon the question of economy in heating. If we assume that outer air brought into a cold air chamber is at 15 degrees F., then it will require every hour in the school-room referred to, some 10,000 heat units to raise it to 70 degrees F. or 55 degrees; or nearly 25 per cent. more fuel is required than is necessary to raise the air to 60 degrees, if the heat rendered latent by evaporation be not considered. As some 35 pounds of coal per hour with a loss of 20 per cent. by the chimney is theoretically required to heat a room up to 70 degrees under the conditions we have assumed, it is apparent that the matter is a most important one for consideration.

In this connection, it seems of importance to refer to the part played by radiant heat as an adjunct to room heating. All are aware of the effects of the heat from a grate, but we are not so conscious of the effects of the heat radiated from steam and hot water pipes. We speak of heat waves and are aware of how relatively different are different liquids, solids and gases, in their power to absorb rays of heat, and that amongst gases, the oxygen and nitrogen of the air are non-absorbers of heat, whereas, as Tyndall informs us, the absorption of heat waves by water vapor is the chief agent in preventing the earth from becoming barren from the loss of the heat absorbed by the earth during the day. Probably from 10 to 15 per cent. of the heat radiated from the earth is absorbed by the water vapor within 10 or 20 feet of the earth's surface. Such air, too, plays an important part in the absorption of heat in the air of a room when the air has its proper amount of moisture, while further the penetrating powers of the heat rays from radiators and grate fires by which the bodies of occupants are warmed, are well known. Another point of importance in this connection is the fact that a white wall reflects the heat to a much greater degree than dark walls, although not absorbing heat readily itself, and the black steam pipes are much better radiators than if painted white.

We have dealt with some of the physical laws entering into the conditions affecting the heating of the air of rooms, but I have frequently thought that the construction of our houses, which usually have open stairways on three storeys, might be dealt with in a much more economical manner than is usually practised. Most of us know that in a single room, say on the ground floor, the heat near the ceiling is 10 to 15 degrees higher than at the floor, and for the same reasons the air of the lower floors constantly ascends as by a funnel to the upper rooms. In such cases the remedy applied usually is to have a hot air register or a hot water radiator in each room.

Some of our economy hot air furnace manufacturers have, however, seized upon a familiar fact, namely, that by drawing off the air at the floor by a down draft shaft leading to the warm air chamber around the furnace, not only is the air led more equably in each room, but the warm air is kept near the floor of the room and they have with much success solved the problem of equal distribution of heat and economy in the use of fuel. The fatal defect in the system is, that they are re-heating the air already breathed and violating the very first principles of introducing pure air by a fresh air duct in the living rooms. Now, it appears to me that we may make use of the principle of maintaining an equable distribution of heat in the manner referred to, while at the same time utilizing the fresh air shaft by arranging floor ducts so as to lead the foul air from the room into the ashpit of the furnace, with a damper which will turn this foul air into the smoke flue as a cheque draft in mild weather. Indeed I have had this done with much success in the Mission church referred to, insuring a very good ventilation with an excellent distribution of heat in an oblong building.

With regard to the question of moisture, not only can a series of shallow pans in the heating chamber of a hot air furnace be supplied, but evaporating pans under each register may, with advantage, be utilized for still further supplying moisture to air which is abnormally dry.

But dealing with the problem as regards the most practical method of heating a private house and at the same time supplying fresh air there would seem to be no question but that the heating with hot water most completely supplies the several requirements. In the sleeping rooms radiators may be placed, while the window is drawn down, and a draft prevented by a drawn blind fulfills every requirement. For the living rooms each should be supplied with a radiator, while fresh air would be brought into a cold air room in which is a series of radiators over which shallow pans are placed with an automatic supply of water while there will be delivered by the indirect method an ample supply of fresh warm air with adequate moisture for maintaining the air of the room at a normal humidity.

The question of steam heating for large buildings naturally must be considered, and in the matter of economy of installation leaves little to be desired. But except as a means of heating fresh air to be supplied by ducts with a fan, it presents all the difficulties of lack of ventilation and dryness of air which have been already referred to. When thus utilized with small radiators in rooms as supplementary heating in very cold weather, it probably is the most readily applicable of all methods, but the disadvantages of heating houses by radiators are numerous, and cannot be said to be a desirable method of heating, while defective in the total absence of adequate ventilation and supply of moisture. Equability of temperature is not possible, while the cracking due to condensed steam is most undesirable. Probably the ideal method of heating such large buildings is that where steam pipes are used for heating cold air to be delivered by fans with adequate exit shafts, while the steam is carried to coils placed in tanks of water at convenient points for each suite of rooms, from which hot water pipes are carried to the coils or radiators which heat the several rooms as a supplementary means of heating. I have, however, referred to some of the many difficulties no doubt experienced by all, and have touched upon some of the possible remedies. One, however, must recognize the difficulty of having remedies applied. In too many cases we have to take what is in the market, and as I witnessed last year, in some specifications for school buildings, the details were left so indefinite that it seemed likely to become a question of what furnace manufacturer could satisfy a trustee that he could get enough of heat into the building, and not whether they would be ventilated when heated. It does seem very essential that at any rate in public buildings not only should there be laws defining certain necessary conditions before school buildings, &c., could be constructed, but that, as in Massachusetts inspectors should be employed to examine the proposed methods of heating before they be installed.

The President, resuming the chair, spoke in appreciation of Dr. Bryce's paper, and said he hoped Dr. Bryce would tell the meeting in concluding the discussion, if there were any simple methods by which the quantity of moisture in air can be tested.

Mr. Burke: I am almost dumfounded at the amount of moisture necessary to keep a room in a satisfactory condition. I thought when my furnace was evaporating half a pail of water a day I was getting a splendid amount of moisture in the house. With regard to the practice of the hot air furnace men of drawing all the air from the house, instead of from outside, it is almost suicidal. Another arrangement I have in my house which I think is a good thing—I have exhaust registers in rooms where there are no fireplaces. They are set close to the floor and are carried to flues in the chimney stack which are warmed by the furnace and kitchen flues. I find they are acting in a very satisfactory way.

The President: I am glad to say I can go one better than Mr. Burke, I evaporate in my furnace one pail of water a day, but I confess that is one-fifth of what I ought to do.

Mr. Dick: In dealing with a question of this nature architects are generally confronted with the question "what is it going to cost?" I recently noticed an article in the American Architect with regard to the cost of ventilation, and I should like to read it. The article is a portion of a lecture delivered by G. A. Suter before the Engineering Society of Columbia University:

"The total cubical contents of this room are 30,000 cubic feet; the total direct radiating surface in the room is 350 square feet, and the total steam consumption or proportionate boiler capacity required for the heating of this room in zero weather is 3½ horse powers. The moment, however, that you ventilate this room, renewing or replacing the air six times each hour, supplying 180,000 cubic feet of fresh air per hour, we require not less than 9 horse power of steam, when the outside temperature is at zero, to warm this quantity of air from zero to 70° F., or room temperature, and in addition thereto, 2½ horse-power for the mechanical effort required to move this quantity of air in and out of the room. Therefore, out of the total of 15 horse-power that are required for the heating and ventilating of this room, only 3½ horse power are required for heating while 11½ horse power are required for ventilation. Similarly, out of a total of 3,550 horse power required for warming and ventilating these buildings in zero weather only 560 horse power are required for the direct heating, while 2,990 horse power are needed for ventilation. When the out-side temperature is higher these quantities are correspondingly less, except that the motor power, of course, remains constant. For example at 35° outside temperature, out of a total power of 2,017 horse power, the direct heating requires 280 horse power, the ventilation 1,102 horse power for heating the air, and 635 horse power for motive power, or 1,737 horse power for both. The proportionate amount of power for ventilation, as compared with the total power, increases as the outside temperature increases, and, as our average temperature during the heating season is not far from 35,° it is fair to conclude that the ventilation of these buildings costs about six times as much as the heating. This gives us a clear illustration of the cost of ventilation, and an explanation of why, even when the apparatus is provided, the ventilation is somewhat curtailed. We sometimes wonder why our public buildings are not better ventilated, but the explanation, when it is not due to ignorace or incapacity, is found in the expense of the apparatus and in the expense of operation."

In buildings in which the ordinary fan system is provided for exhausting the air, and having a certain amount of direct radiation in the rooms and a certain amount of indirect in the basement for the purpose of warming the fresh air, I have noticed that the whole system of ventilation is often allowed to fall into disuse. For instance, the manager of a bank once asked me if I could not make an opening into his room to get some fresh air into it. I said, "You have a fan; do you use it?" He said "I really do not know. I must see about that." There are some buildings in this city which have excellent systems of ventilation and in which the ventilation is notoriously bad, and I am told that the reason the ventilation is bad is that the apparatus is not used simply on account of the cost of the power for running the fans, and also of the increased amount of fuel necessary to warm the fresh air that must be taken in to replace the foul air taken out. In regard to actual temperatures, I have noticed that with a steam radiator in a room I feel much more comfortable with the temperature at 60° than if it is higher, but when there is no direct radiation in a room, without direct radiation one is apt to feel chilly even if the temperature is a good deal higher. The automatic water supply that Dr. Bryce recommends is an excellent idea, but I confess I had no idea of the large amount of water that is required to properly moisten the air in a room. There is one point I might mention with regard to this: I noticed in my own house that when the water was doubtful (as it has some times been in this city) there was a very objectionable odor in the house, but after awhile I discovered that it was caused by the gradual accumulation of filth from the water at the bottom of the evaporating pan, and a very objectionable odor was sent up into the rooms.

Mr. Edwards: I would like to mention here one thing that has come under my own observation. I once or twice went on a little exploring expedition a year or two ago after having seen a ventilating apparatus in successful operation, and found steam shut off from coils in ventilating stacks and fresh air inlets closed up, and on mentioning the matter to the owners have been told that it was a pity I had not looked around sooner, as they were not aware that the ventilating appliances were not in daily use. In these cases the caretakers had shut off the fresh air and closed up the ventilators simply to save themselves the extra labor in firing up. I believe this sort of thing is more common than one might suppose.

Mr. Langton: The reason why the hot air heaters object to the cold air duct is that to them a cold air duct is a cold air duct. A standard size does for houses of very different sizes and is usually too large for any house. As a matter of fact the cold air duct should be proportioned not so much to the house as to the number of people in it, and it takes a very small cold air duct to supply an average family of six with the 3600 cubic feet per head per hour that the tables of ventilation require, the law being that air enters through the aperture of a duct between outside air and inside air at a rate which is equal to that a body would attain in falling through a space equal to the difference in height of a column of the outside air and a column of the inside air if equalized in density, therefore in cold weather the air enters at a fast rate, and in mild weather at a slow rate, so that in cold weather a much smaller duct is required than in mild weather in order to supply the same quantity of air. I have calculated that for the average family of six a cold air inlet need only be 7″ x 12″ when the thermometer is 40° outside (accepting the inside standard of 70°), and may be reduced to 4″ x 12″ in zero weather. If our ducts were made of sizes carefully regulated according to need they would not be found to cool the house too much. There is something which Dr. Bryce said which I do not understand. The great point made, and a great part of the argument was, that if moist air surrounds our bodies, the radiation from the body is less, and therefore the body is more easily kept warm. How is it that in the North-West where it is so dry they say that 40° below zero is not felt as much as a much higher temperature is here?

AGENTS FOR CANADA

Mr. Kay: Mr. Chairman, it seems to me that this question of ventilation that has been discussed, goes beyond the limits of what is practical. The idea of taking a cold air duct and putting it under the furnace! What would be the consequences? Why, the fire would be uncontrollable, you would be roasted out. The moisture in the air would be burned up. I think there is a great deal of common sense in the use of an interior cold face when it is placed near the front door. The air at that part is cold; every time the front door opens there is a great deal of fresh air comes in which goes down the cold air pipe, so that there is plenty of fresh air supplied in the course of a day. I find by experience that warm air ducts must be on the inside, in some internal partition, in a brick partition; if we have not a brick partition we must make them out of tin.

The President: In regard to that point of too large an amount of supply of air to the furnace, you need not use all the air, but divert part of it into the smoke pipe.

Mr. Gordon: I don't know, Mr. Chairman, how long time you wish to devote to this discussion, and I think it is proper at this stage to very enthusiastically and heartily move a vote of thanks to Dr. Bryce for the very instructive and practical paper which he has given us. In common with a great many others here I have been thinking of my past sins and making promises that I am going to do better in the future, and that in itself is a good thing for the doctor to have secured. I am sure we will all remember the impetus he has given us. I am impressed with the large amount of moisture required. I have been trying for two or three winters in my own house a plan of supplementing the evaporating pan at the furnace, (which, by the way is nearly always placed too low down to render efficient service) by suspending ordinary two quart tin cans under the floor registers and having them filled each day. It is astonishing with four or five of these in a house, what a large amount of water you can evaporate. However, I was just thinking, in fact I was speaking to the doctor before coming in here of the way in which the present generation seems to be enfeebled and subject to disease more than our fathers and grandfathers used to be. We have our houses built so much better than they used to; we fit our sash so much tighter; we try to save fuel in that direction, and make our houses as hot as possible. We put in hot water heating apparatus, and in many cases without any indirect radiators and fresh air inlet. I have been insisting (even with small apparatus) on having at least one indirect radiator under the hall. I have been trying a plan of putting a pan over the indirect coil under the hall and a water pipe brought there, so that by turning the tap a little every day that pan could be kept full. But since I have been learning of the immense amount of water required, I have been considering if it would not be desirable to have upon that a ball cock, so as to keep the pan automatically filled.

Mr. Belcher seconded the vote of thanks. I am a friend of Dr. Bryce. I noticed that he spoke of the low rate of diphtheria in my native country. Possibly he may recollect that the winds are from the west and they blow from the Atlantic right over the country. Of course we get the moisture from the ocean saturated with salt, and that coupled with the fact that we have no furnaces, and there are no heating apparatus but the fire-places, may account for it. Where in every room there is a fire-place, and the fire is kept burning in every room, it is impossible to get heat without at the same time getting ventilation and an abundant supply of fresh air which in Ireland is moist.

Mr. Baker: In attempting to speak to this immense question, I find my mind in a most chaotic state indeed. The paper I think is the best paper we have ever had. It is practical from beginning to end. We cannot fail to understand it. It brought out, for my part, the points I have been trying to get at through reading, and has condensed for me a great many books. Taking the tables which have been put upon the blackboard by Dr. Bryce, in the first column we find that a person who is run down should take a sea trip as we see that the air in mid-ocean contains only .06 bacteria per cubic meter. Following that down I am staggered by the figures, when in the city of Paris 36,000 bacteria per cubic meter are given off by an old house. Now that should be advertised; that is a point for us, sir. We have a reporter here, and he should devote a column to that. It makes it clear that we should not live in an old house, that we should have a new house! Taking the next paragragh on the black-board it would appear that we ought to live in wooden houses if we are to live economically. I also would think that perhaps a wooden house would be more wholesome to live in. It is very interesting to note the different points brought out there of the different powers of conducting heat, of the several materials. Passing on to the question of moisture, we have another peculiar proposition, that is this: We find that in London since artificial means of heating rooms other than fire places have been introduced, the ratio of diphtheria cases has greatly increased owing to a sufficient amount of moisture not being supplied. Now it has been pointed out to us that the residents of Ireland who have only fire-places are all in old houses. The individual who lives in the old house has more moisture and more microbes, while the man who lives in a new house has less moisture and fewer microbes; a choice of two evils with the benefit of the doubt in favor of the new house; henceforth we should see that he gets the necessary moisture. Dr. Bryce referred to painting of radiators. I think we all know that bare iron radiates heat more than that which is in any way finished outwardly. I remember on one occasion when I travelled up to the park to speak to Dr. Bryce on this question of heating and ventilation, he described an ingenious device which he had successfully used to equalize the temperature of the air throughout the room; if he has time perhaps he will describe it to you now, as I am sure you would be interested.

The President: We have this motion before us. I know Dr. Bryce will recognize that although it is a formal motion, it is one that is sincerely made. I am

Canadian Industries and Canadian Products are taking the lead the world over. Why should not Canadian Varnish do so at home? When making out the specifications for your next building, remember that

only afraid that when our municipal authorities learn the amount of water that is being used, they will raise the rates on us. You will please show your approval of this motion. Carried.

Dr. Bryce: Mr. President and Gentlemen: I know your time is limited, and I am sure you have had quite enough from me without discussing the points that have come up, yet there are several that need to be answered. The ventilation especially in the schools in the city of Toronto, attended by 35,000 children, is criminally neglected. Naturally one gets interested in the question. After all a health officer is not a health officer until he runs into actual contact with all the problems affecting the health and comfort of all the citizens, and that is what I have been trying to do for eighteen years, and in the question of ventilation, I may say that this generation in my judgment, is farther back than it was eighteen years ago. We recognized years ago that there ought to be an honest attempt to get outdoor air into rooms; to-day we have forgotten it, and we have been led into the idea that a hot air furnace may be allowed to give us the same air over and over again. I have pointed out in the table which Mr. Baker has referred to the relative purity of air outdoors and in, and if we have many diseases of a communicable character, that the number of germs in a house is an important factor. It is further true that an old house which has been accumulating dirt for a number of years must necessarily be a dirty house. Undoubtedly a hospital is a dangerous place to try and get well in. I recognize the point that Mr. Dick has brought up with regard to cost. No one can doubt that in this country. I am as convinced as I can be of anything that if we realized that the air which is up there at the ceiling is 15° warmer than it is here, that we would endeavor to economize by adopting means whereby it may be kept near the floor thereby economizing heat. Mr. Langton says that a person in Calgary is not supposed to feel the cold there as much as in Toronto. It is perfectly true, and if Mr. Langton will watch these figures for a moment he will see a partial explanation of the fact. We have got a loss of heat from the body. As we all know moist air conducts heat rapidly while dry is a non-conductor. Further, if it be remembered that the air of Calgary is usually dry and cold, capable of holding very little moisture, we will see why a man's body does not lose much by evaporation. If I have aroused an interest in what seems to me to be a very practical subject, I will feel myself compensated for any trouble I have had in preparing the paper. There is a practical question asked by Mr. Burke which I neglected to answer. He asked how we are to find out the humidity of rooms. You need only to arrange the ordinary dry and wet ball thermometer and with a set of tables may determine the relative humidity readily.

Mr. Burke: Can you introduce too much moisture in winter?

Dr. Bryce: If you get up beyond 75 or 80% you would probably have too much, because you are going to lose heat unduly by a damp air. The difficulty is the other way, because in all artificially heated houses we do not get the moisture.

Mr. President: I think that it is a generally understood thing that we do not confine our members on the Council to the city. There is just one difficulty that if we get too many outside of the city we have a difficulty in getting a quorum. There have been generally two members of the Council who are not Toronto residents.

Mr. W. R. Gregg: Read letters from Mr. Dick and Mr. Gouinlock withdrawing their names from the list of nominations for Council and from Mr. Baker resigning from Council. Under pressure Mr. Baker withdrew his resignation.

The election of members of the Council was then proceeded with, resulting in the election of Messrs. Edmund Burke, Lawrence Munro, of Hamilton, and Eden Smith.

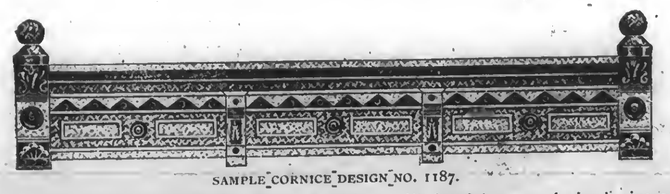
The convention then closed.

At a subsequent meeting of the Council the following officers were elected:—President, Grant Helliwell, Toronto; 1st Vice-President, F. S. Baker, F.R.I.B.A., Toronto; 2nd Vice-President, John A. Pearson, Toronto; Treasurer, W. A. Langton, Toronto; Registrar, W. R. Gregg, 94 King street west, Toronto. Council:—Fred Henry, London; A. H. Gregg, Toronto; Lawrence Munro, Hamilton; Edmund Burke, Toronto.

Ornamental Metallic Finish

Foremost among practically popular goods for decorative finish and superior utility, are our

Metallic Cornices
Metallic Sky Lights and
Crosses and Finials



SAMPLE CORNICE DESIGN NO. 1187.

In Cornices we make many stock designs, and in addition will furnish any desired size or shape to order—your choice is unlimited.

Our Metallic Skylights are made with hollow bars of galvanized steel or copper—supplied in any size or style—for any roof.

Our Crosses and Finials of all descriptions are made of copper or galvanized steel—furnishing graceful designs to suit all tastes and purposes.

All these goods are light in weight, easily handled, fire-proof, and pre-eminently satisfactory for all types of buildings.

Consult our Catalog for full and interesting information.

Supplies for South Africa.

THE quantity of food and other supplies required by the British Government for the South African campaign is enormous. Many classes of supplies, such as canned goods, hay, cheese and bacon, flour and salt, portable houses, wagons, bicyles, axes, etc., Canada could supply, but the bulk of the orders seem to go to the United States. As an example the war office is said to have just contracted with a United States firm for 3,000 axes. We have given British manufacturers a preference in our market, and should have a claim to British orders for products which can be as well supplied by Canada as by the United States. If the British Government are ignorant of our ability to supply many of its requirements blame attaches to the Dominion Government, and no time should be lost in putting before the home authorities the fullest possible information regarding the character and extent of our resources.

Financial Result of the Paris Exhibition.

THE footing up of accounts in connection with the Paris Exhibition indicates that if there be a deficit at all, it will be but a small one, while possibly there may prove to be a surplus—depending upon the willingness of the city to purchase certain improvements of a permanent character on the banks of the Seine. The cost of the buildings and other works was $18,000,000; the expenses of administration $1,700,000; policing, lighting, etc., $2,500,000; "unforseen expenses" nearly $10,000,000; miscellaneous expenses, $250,000, a total of $23,450,000. The receipts from all sources, including subscriptions of $4,000,000 each from the city of Paris and the Government of France amounted to $23,050,000, leaving a deficit of $400,000. This is a much better showing than was made by the French Exhibition of 1878, when the receipts fell short of the expenditure by six million dollars.

The School of Practical Science.

ATTENTION was called in these columns recently to the overcrowded condition of this school, and the urgent need for increased accommodation and equipment. During the present month this need has been forcibly pressed on the attention of the government by a petition presented by the students of the school. The prayer of this petition was strongly supported by deputations representing the Toronto Board of Trade, the Ontario Association of Architects, and the Canadian Manufacturers' Association. Emphasis was laid on the necessity of providing adequate educational facilities for the large number of young men who are desirous of qualifying themselves to fill the more lucrative positions in the rapidly developing industrial enterprises of this country, which positions are at present too frequently occupied by graduates of foreign scientific schools. As an illustration of the present overcrowded condition at the School of Science, the fact was mentioned that the present first year class in chemistry, numbering 120 students, had to be divided five times. The Premier admitted that means must be found to increase the ac-

commodation and efficiency of the school, and that at the present rate of expansion a new building would soon be the only remedy. The cost of a suitable building, together with the necessary additional equipment and teaching staff, was placed at about $300,000. The government would seriously consider what action should be taken and from what source the necessary funds could be obtained.

A Dominion Exhibition.

THE Dominion Government is said to have appropriated large sums of money to cover the cost of Canadian exhibits at the Glasgow and Pan-American Exhibitions. A large sum was spent for this object at Paris last year. We are not disposed to question the wisdom of these expenditures. It is good business policy to advertise to the world the character and extent of our capabilities and productions, thereby inducing increase of our population and investment of capital. Why should not this be supplemented by the holding of a Dominion Exhibition in Canada and the effort to induce foreigners to come and actually see for themselves the kind of country we have and the greatness of its resources? We cannot hope to carry out an exhibition on the scale of those held at Chicago and Paris, nor should the attempt be made. Our natural development has reached a stage, however, which should warrant us in entering on an undertaking of this character on a properly proportioned scale. The Dominion Government last year refused to assist such a project, perhaps because of the large expenditure that was felt necessary to secure adequate representation at the great international Exhibitions at Paris, Glasgow and Buffalo. Next year when these shall have passed out of sight the subject of a Dominion Exhibition should receive practical consideration, and the Federal and Provincial Governments which for many years have been spending money on Exhibitions got up by and largely for the benefit of other countries, should make a liberal appropriation towards a Canadian Exhibition to be held in Canada, which the mother country, our sister colonies and our neighbors across the line should be invited to visit and send exhibits to. We have the nucleus of such an Exhibition at Toronto, and in connection with the proposal to erect new buildings the larger project should be kept in mind. It is doubtful if the property owners of the city whose approval must be obtained will sanction the proposed large expenditure for new buildings until just cause of complaint with the management of the Exhibition shall be remedied. If the project of holding a Dominion Exhibition in the near future is to be proceeded with it would be desirable to defer action with regard to new buildings in order that a comprehensive scheme adapted to the larger requirements might be formulated.

Fire Escapes.

The injury and narrow escape from death experienced by employees of factories in Toronto recently owing to the absence of means of escape from burning buildings, has been the means of directing public attention to this important subject. It appears that the Factory Act, which stipulates that factories must be fitted with fire escapes, delegates to the government factory inspectors the duty of enforcing observance of this provision. The matter is thus taken out of the control of the city council. It is quite evident that the government inspectors have entirely failed in their duty in this regard. In consequence the lives of thousands of workmen and workwomen are daily in jeopardy. The subject has recently came up for discussion in the Legislature, and amendments are to be introduced which are designed to ensure efficiency, in the operation of the law. In a timely letter to the press Mr. A. J. H. Echardt has called attention to the necessity of providing the public school buildings with fire escapes. He instances schools of three and four stories without fire escapes and with only one stairway leading from the bottom to the top, which, in the event of fire starting in the basement, where the heating furnaces are placed, would act as a flue to carry the smoke and flames to the upper stories. The writer very correctly states that the ordinary iron five ladders attached to the outside of the school buildings would be of little or no use, but that the proper thing would be to have the back part of the school built out, or a separate tower built, with a stairway as wide as the main one, reaching right to the ground, with doors leading to this stairway from each flat, so that in case of a fire in the front stairway the pupils could be got out by the back way, so making a double exit, which the children could use with swiftness and safety. The school authorities seem to rely at present entirely upon the fire drill, which is a useful means of preventing panic in the event of fire and also under some circumstances of securing the safe exit of the children from the building. It would however be useless as a means of saving the lives of children on the second and third floors, should exit by the single stairway be blocked by smoke and flame. No time should be lost in providing a more adequate safeguard.

Methods of Heating in Relation to Health and Economy

THE paper presented by Dr. Bryce, Medical Health Officer for Ontario, at the recent annual convention of the Ontario Association of Architects, and which was printed in full in our February issue, contains much valuable information which architects and manufacturers of heating systems, as well as the public, would do well to study and carefully consider. The author of the paper lays special stress on the necessity for greater attention to ventilation in connection with heating. Further than this, he shows very clearly the necessity for a proper degree of moisture to be maintained in the air of living rooms. It is not only that there shonld be a proper supply of fresh air introduced, but what is quite as important, that this air should contain a proper percentage of moisture. Dr. Bryce stated that where this percentage of moisture is not supplied, the air takes up moisture from every available source, including the bodies of the inmates of the building. He pointed out that in a school-room, for instance, where the air was not sufficiently moist, part of the necessary moisture was obtained from the mucuous membrane of the children, thus leading to irritation of the membrane, and rendering the children very susceptible to disease. Here may possibly be found one source of the spread of diphtheria and other diseases of an infectious nature to which children are specially subject. Apart from this effect upon health, it appears that moisture in the air has also an important bearing upon economy in fuel. The author of the paper referred to stated that the inmates of a room, the air of which contained a sufficient amount of moisture, would be comfortably warm with the temperature at 60 degrees would the inmates of a room with dry air at a temperature of from 70 to 75 degrees. He estimated that to raise the temperature from 60 to 75 degrees would entail an additional expenditure for fuel of 25 per cent. These, and other statements, made a decided impression upon those who heard the paper read, and, in view of the importance of the subject, we have thought it advisable to call the special attention of our readers to it.

The Commercial Position of Great Britain.

FOLLOWING closely upon the announcement that Russia has increased its tariff on United States goods, comes a despatch from London that as an outcome of the inroads of American manufacturers upon British trade there is being formed the National Federation of Master Associations and Trades Unions to educate the minds of employees and employers in respect to the expansion of British trade, to devise means to meet foreign competition, to send joint deputations of capital and labor abroad to enquire into the conditions of other countries, and to provide a federation where employers and employees may meet on the same plane. This movement is under the leadership of Mr. John Lockie, late conservative member for Devonport, and is said to have the approval of the present British government.

The United States have not only become a strong competitor for the foreign trade of Great Britain and other European nations, but have also invaded the British market, and are securing a large share of the home trade. It is stated that in one industry alone (the manufacture of boots and shoes) Great Britain's trade last year was less by $5,000,000 than in the preceding year, notwithstanding that the firms engaged in this industry are said to be among the most progressive and enterprising in the way of adopting improved machinery and other manufacturing facilities. The American manufacturer takes infinite pains to adapt his goods to the requirements of the particular market in which he seeks to sell, and by liberal advertising and persistent push keeps their merits before the notice of prospective buyers. In Great Britain there are many long established businesses which have descended from father to son. This has in many instances induced the idea that the system of management and character of goods that have been successful for so long a period may safely be continued. Rapid and startling changes are, however, taking place throughout the world, bringing changes in methods and requirements of the people. The nation that studies most carefully these changes, and constantly adapts its products to the new conditions, is the one which will obtain and maintain commercial supremacy. In this regard the United States seem to stand foremost to-day among the great commercial nations of the earth, hence the strides they are making in the development of their foreign trade.

It is gratifying to note that Great Britain is awaking to the situation and considering ways and means whereby she may hold her commercial position. History has shown that the British people when once aroused are prompt to act for the protection of their interests whether territorial or commercial. Prompt, intelligent and thorough enquiry into the subject of Britain's commercial facilities and relations with other nations would seem to be a present and important necessity, and should be followed by equally prompt, intelligent and thorough reforms in methods, where such are found to be necessary.

The United States exports to Great Britain and Ireland are valued at $600,000,000 per year, while the value of the imports from Great Britain into the United States is but 25 per cent. of that amount. The United States exports to Canada for the fiscal year ending June 30th, 1900, were valued at $109,844,378, or more than the combined imports of France, Australasia, Austria-Hungary and Russia. While profiting so largely by British and Canadian trade, the United States continues to maintain a high tariff wall against these countries. The time seems to have arrived when freer access should be demanded by Great Britain and her colonies to the United States market, and in default of reciprocity of trade there should be a nearer approach than at present to reciprocity of tariffs.

Great Britain has in her colonies commercial allies which as yet she has scarcely taken any steps towards reaping the advantage of, but which, if brought into closer relations with her, would greatly assist in extending and maintaining her commercial supremacy. Canada has shown a desire to enter into such relationship by giving a substantial preference to British goods entering this market. That this action has not resulted in greater advantage to British manufacturers is largely due to the failure of the latter to make their goods better known in Canada, as well as to adapt the goods to our requirements.

Another phase of this question, as seen by an American writer, is presented in the following extract from the Engineering Magazine, of New York: "To the outside world the most impressive lesson of the Queen's death is the magnificent stability of British institutions and the British commercial system. Not a wheel stopped, save as a token of reverence; not a tremor in values disturbed financial centres; not an uneasiness or uncertainty as to national politics caused business undertakings to waver or hesitate. Compare this with the quadrennial upheaval in the United States, where economic legislation of every kind is the football of politics, and industry follows with uncertain feet now artificially raised on an unstable platform of protection, now sinking back from the morass of free silver, certain of nothing but uncertainty with every change of chief executive. The "demise of the Crown" demonstrates anew England's industrial strength, and those who are ready to cry her downfall before her industrial rivals would do well to remember that this stability of commercial organization outweighs much mechanical aptitude. Machinery can be bought, skilful brains and hands can be hired; but stable, political and commercial systems are of slow growth, and not soon attained."

A conference of Australian architects has been held for the purpose of forming a Federal Institute. In order to aid in the promotion of education it is intended to establish a travelling scholarship.

The Canadian Manufacturers' Association have requested the Mayor of Toronto to call a meeting of representatives of various organizations, such as the Board of Trade, the Trades and Labor Council, Ontario Association of Architects, the Guild of Civic Art, to prepare a plan for the beautifying of the city as a Victoria memorial.

REDUCING THE FIRE LOSS IN BUILDING.

By Edmund Burke.

To put the matter in a nut-shell, the best means of reducing the fire loss would be the conversion of the insurance companies to more scientific examination and classification of risks.

Rooms of the Ontario Association of Architects and Toronto Engineers' Club, 96 King Street West, Toronto.

It is useless to argue that strict civic by-laws should be enacted. The Ontario Association of Architects through the local organization in Toronto, made a serious effort in this direction three or four years since, when endeavoring to have the city by-laws revised and improved. They were immediately confronted with objections by real estate owners, aldermen and builders. These affirmed that the increased cost which would be involvedby the adoption of proper and scientific methods of fire resisting construction would put an effectual damper on building operations. The good intentions of the architects, as a consequence, came to naught. It maybe taken for granted that the only way to effectually reduce fire risk is to appeal to the pocket of the building owner by means of decidedly low rates of insurance on classes of buildings which absolutely conform to the best known methods of fire resisting construction.

Rooms of the Ontario Association of Architects and Toronto Engineers' Club, 96 King Street West, Toronto.

There is no doubt but that the total volme of insurance would be reduced were such methods adopted, while on the other hand the fire losses would be much less, and the net profit of the underwriters greater.

The same unity with regard to risks, as that now exercised in the imposition of rates, should result in immediate and great improvement in methods of construction.

It may be asserted that it devolves upon the architect to introduce better methods. The true architect, who has the safety and welfare of the community at heart, is only too glad to adopt the very best methods, but in ninety nine cases out of the hundred his hands are tied by his employer; he is told that it is folly to add twenty, thirty or forty per cent to the cost of a building when there is but little difference or advantage in rates of insurance. The desire of the building owner is to obtain the greatest return for least outlay, and he will naturally object to enter into any increased expenditure which will not bring corresponding returns. The lightly built cheap building of the usual fire trap construction, generally returns, for a time, the best net income, and he therefore prefers and insists upon the erection of that class of building.

It should be borne in mind that every fire resisting building is a boon to the community. It is an efficient fire stop, and reduces the fire risks for a considerable radius in the neighborhood. Every additional building of the kind is a further safeguard, and were such buildings sandwiched freely among those of even the most flimsy construction, no very extensive and wide spreading conflagration could occur.

Rooms of the Ontario Association of Architects and Toronto Engineer's Club, 96 King Street West, Toronto.

The greatest encouragement, therefore, should be given to those who are willing to erect buildings of the best class of fire resisting construction.

Fire hazards may be divided into two classes, external andinternal. With regard to external hazards, the fire loss in buildings would be very appreciably reduced were more attention paid to the protection of the window openings. The complete destruction of the inflammable interior fittings and stock of a large fireproofed departmental store in Pittsburgh, was chargeable to a fire in an adjoining building and unprotected window openings, as was also the burning out of a portion of the interior of the Home Life Insurance Co. in New York City. The latter building was considered one of the best of New York's fireproof buildings, but an external fire attacked it in a weak spot. If the windows in the light well overlooking an inflammable building close by had been properly protected no serious damage would have occurred. The standard wooden shutter covered with tin is the most reliable protection.

Woven wire glass set in metallic sashes, which are hung with chains in metal frames are superseding the wooden tin covered shutter in many instances.

The advantages are that the light is never shut out, they are not so liable to be left unclosed, or carelessly left open, as is the case with the shutters, and if a fire starts behind them it is not concealed till it has obtained great headway.

Where greater safety is desired the glass may be doubled, giving almost as good protection as the shutters; the tin covered shutters, however, are required for certain of the most severe risks.

Wire glass is, of course, practically out of the question on street frontages.

Rooms of the Ontario Association of Architects and Toronto Engineer's Club, 96 King Street West, Toronto.

Rolling metallic shutters are occasionally used, but the cost, and the time and trouble required to open and close makes their general use impracticable.

The water curtain is another device for the protection of external openings. It has been used in very few buildings, and it is a matter of surprise that owners

and underwriters are content to expose enormous stocks to the frail protection of sheet glass, or plate glass of large area which may be shattered on every storey in an instant, allowing the heated gases, if not the flames, of an adjacent fire to cause instantaneous ignition on several floors simultaneously.

The severity of our climate in winter presents a difficulty in the application of the water curtain. It is necessary to use what is called the dry system, the piping being kept free of water till it is required.

Among the other external appliances for reducing fire risks may be mentioned stand-pipes, which are carried up to the roofs of tall buildings, with attachments near the sidewalk for connection from steam fire engines or city pressure.

The provision for fighting an external fire from the roofs of the Eaton establishment undoubtedly saved those premises during the progress of the Simpson fire in Toronto in 1895. The internal hazards cover a large range.

Probably the greatest fire loss is occasioned through large undivided areas, not only horizontal but vertical. Until strict and undeviating rules are enforced reducing the area of all compartments containing inflammable material or goods, the fire loss will be abnormal. The structure itself may be built of the most approved fire resisting materials, but this will not save the contents. In fact there is danger that the burning of the contents, if great enough in volume, will wreck the building or so seriously damage it that extensive repairs or reconstruction will be involved.

It is equally necessary for the reduction of the fire loss that staircases and elevators should be entirely enclosed and cut off from the building by fireproof walls and automatic fireproof doors.

The height of buildings has a direct relation to the proportion of fire loss. It is practically impossible to control a serious fire with present appliances in a building of more than four storeys, or say 45 to 50 feet in height. Buildings of greater height should be built of fire resisting materials, divided into compartments of restricted area, and equipped with automatic sprinklers.

The partitions forming these compartments, to be thoroughly effective, should be constructed of brick walls stout enough to stand the hardest usage. The openings in these partitions should be protected with automatic fireproof doors, double for absolute safety.

Thin partitions of 4″ terra cotta blocks or concrete on expanded metal in fireproofed structures are sufficient under certain conditions, such as for the sub-divisions in office buildings and places where large accumulations of inflammable material are not permitted. These partitions, as usually constructed, are often a delusion. They have wooden door posts, heads and transoms and sometimes wooden sill pieces which may burn out and wreck the partition. Frequently all the hall partitions in an office building have large openings in the upper third or fourth of their height, filled with ordinary glass which offers no obstacle to the spread of fire between the rooms and halls. To be effective the glazing should be of wire glass in metallic frames, and the framing and doors of metal or protected wood.

The abolition of hollow floors and partitions would greatly reduce the fire loss, as all concealed spaces become flues for the rapid carrying of fire and smoke from one part of a building to another.

The strapping of floors and ceilings for the removal of the foul air from buildings heated by certain descriptions of hot air apparatus has furnished one of the most glaring examples of hazardous construction which it is possible to conceive. The whole building, under this method, is honeycombed with a network of concealed and continuous spaces, and but a spark is needed to reverse the current and carry the fire, almost instantaneously, to every section of the structure. Happily this system of ventilation is becoming obsolete, and none too soon as far as safety from destruction by fire is concerned.

The abolition of hollow construction and the adoption of solid floors and partitions is entirely feasible in all but exceptional cases, and even in these certain precautions in the way of fire stops could be introduced.

All external wood bracketting, cornices and other exposed woodwork, especially at considerable height, should be abolished; as good an effect can be obtained with metallic mouldings secured to wrot. iron bracketting or frame work.

In the so-called fireproof buildings too little attention is paid to the protection of the girders and columns. The floors are usually of a most solid description, but the parts referred to, which receive the first and greatest impact of heat have frequently but a thin veneer of fire resisting material which breaks or scales off permitting the heated gases to warp and twist the structural members, to the destruction or distortion of the building.

The fire loss could be reduced by constructing each floor as a watertight unit. The damage to the contents of lower floors by water only must constitute a large proportion of the fire loss.

It must not be forgotten that the inflammable wood trim and the contents of the best fireproof building ever constructed will burn if ignited. Few fires would spread if the first pail of water could be applied at the opportune moment.

One of the very best means of reducing the fire loss is the automatic and early application of water. This is accomplished by the installation of automatic sprinklers. Every foot of the premises to be protected should be covered making the spread of fire almost impossible under any but the most extraordinary circumstances.

Another important method of reducing the fire loss would be closer inspection of alterations. Frequently an otherwise safe risk is made a very bad one through structural changes in after years, sometimes made by or for tenants or others unacquainted with or careless of the original scheme adopted to make the hazard a safe one.

To sum up, "the best means of reducing the fire loss" lies largely with the fire underwriters who should encourage the best class of fire resisting buildings by adopting specially low rates for such, with penalties or increases for every infraction of well defined rules in connection with standard methods of construction and equipment.

The standard building carrying the most favorable rates should be absolutely fireproofed in every particular. The walls should be of brick or terra cotta, the columns; girders, and beams should be amply protected with terra cotta of good thickness, having air spaces, and so secured that displacement will be impossible. Little or or no wood should be used for floors and trim.

The building should have no large unbroken areas; brick or terra cotta partitions should divide it into sections of moderate size. Stairs and elevators should be completely cut off from the rest of the building with fireproof enclosures and doors. Floors should not be pierced with well holes. Exterior openings on areas, lanes, etc., should be protected with wire glass in metallic sashes or with tin-covered shutters, and those on street frontages with rolling metallic shutters or water curtains. Stand-pipes should be run from sidewalk to roof. A sprinkler equipment should be installed, and each floor should be made a water-tight unit. If the building is of such a height that the city service will not protect the upper storeys a special pumping plant should be installed with stand pipes and hose on every floor and on the roof.

An ascending scale of rates from a very low minimum rate should be adopted, placing adequate penalties or fines in proportion to the departure from the standard of safe building.

High buildings not fireproofed or protected by sprinklers and shutters should be discriminated against by extra high rates.

Buildings having beams and joists of wood should have open construction, avoiding closed spaces. The joists should be heavy and set a good distance apart, carrying heavy plank floors. All spaces caused by furring out or strapping should have frequent cut-offs or fire stops. The areas should be divided as in fire resisting buildings, but with even greater care and of less size. Elevators and stairs should also be similarly cut off.

STUDENTS' DEPARTMENT.

TORONTO ARCHITECTURAL EIGHTEEN CLUB.

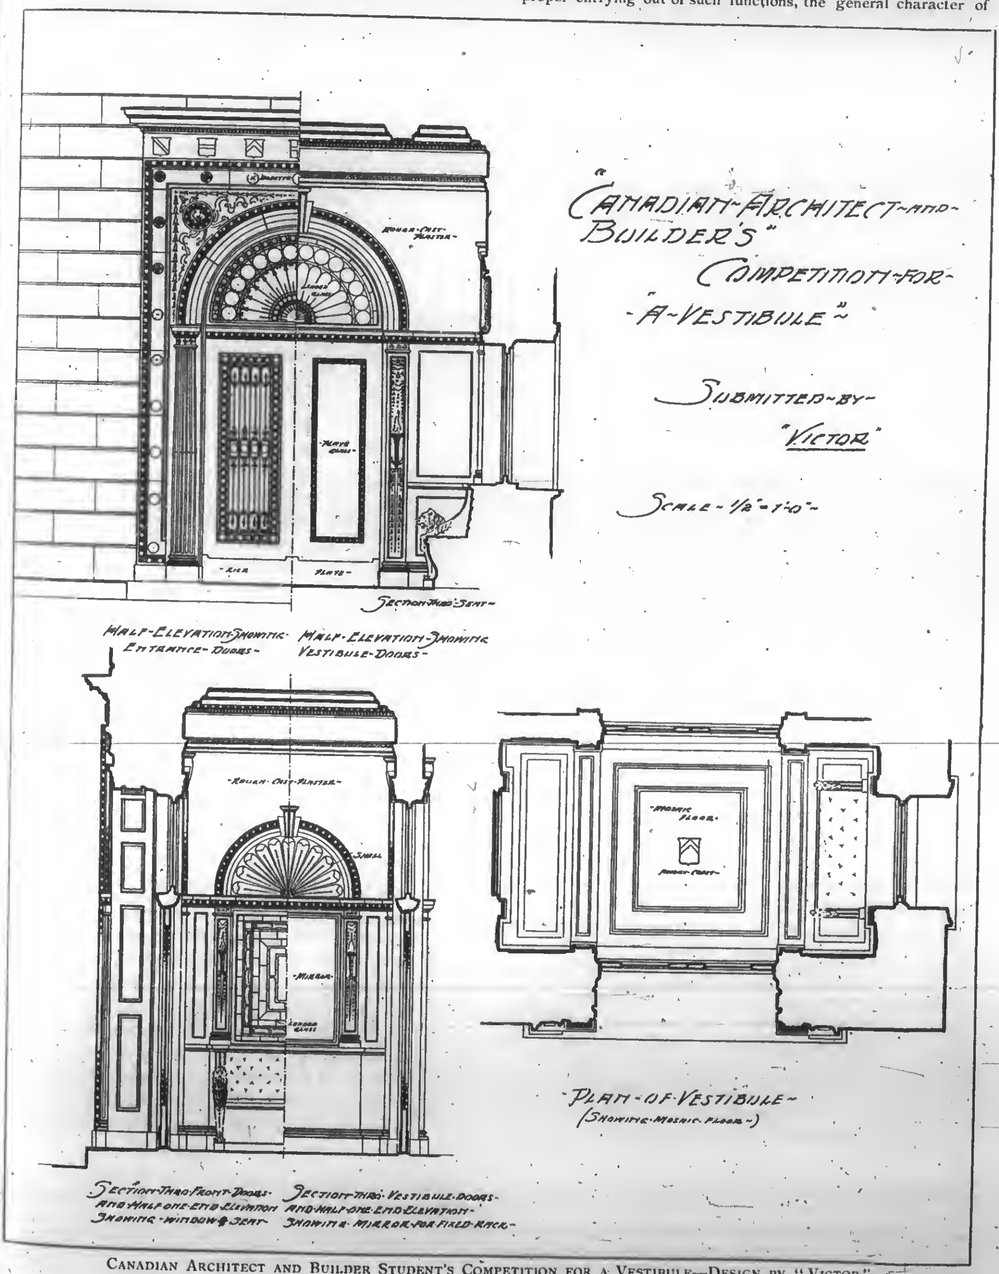
The Club have affiliated with the Central Ontario School of Art and Design, of which they will form the architectural section. Rooms have been secured in which to carry on the educational work in behall of students. This work is under the direction of an Executive Committee of three. The Committee have appointed six patrons who will act as instructors to the classes, of which three have been formed—one primary and two advanced.

Three meetings have already been held with an average attendance of about fifteen students. The rooms are at the disposal of students for study at all times. Criticisms of the students's work will be given by the instructors on Tuesdays and Thursdays.

The following is a programme of the first problem in design:

"A Casino on a wealthy gentleman's wooded estate. The building is to be constructed of stone or marble.

"The casino is to be used chiefly in summer time and will be a building of a monumental character. Concerts, dances, etc., will be held there, and accommodation must be provided for the proper carrying out of such functions, the general character of



CANADIAN ARCHITECT AND BUILDER STUDENT'S COMPETITION FOR A VESTIBULE—DESIGN BY "VICTOR" (MR. WILLFORD A. GAGNON, MONTREAL), AWARDED FIRST PLACE.

such a summer casino should be well considered in the plan.

"A stream runs through the estate, and a building may be placed so as to take advantage of this in the general scheme of surroundings or not, as the designers see fit. The levels of the grounds are left to the imagination. It is specially desired that this building should have a classic treatment.

"Each student will make a study of his general scheme in plan and elevation of a scale to 1/16 in. to the foot and send a freehand tracing of the same, dated and signed, to the Chairman of the Educational Committee, on or before noon Wednesday, March 6th, 1901.

"As this programme is issued for the purpose of classifying the students, the preliminary sketch will determine who shall proceed with the development of the problem. Those who are not found eligible will be placed in Class "C" or Preparation Class. Those who finish the problem and render, will be placed in Classes "A" and "B" according to the mentions they receive. The drawings sent in finally must conform to the general outline and scheme shown on sketch first submitted. Any radical departure therefrom will debar the student from being given a mention, but not from general criticism. Final drawings to have the plan rendered showing the general arrangement of the immediate surroundings at a scale of ⅛ in. to the foot, the section at the same scale and the elevation at a scale of ¼ in. to the foot, also a drawing of detail at a scale of 3 in. to the foot. The drawings to be rendered in wash with cast shadows. Drawings to be delivered on a date hereafter determined."

The Executive Committee state that arrangements are being made to give instruction in scientific subjects next autumn.

A TWENTIETH-CENTURY ARCHITECT.

By Banister F. Fletcher.

And if this is a correct view of the architecture of the coming century, what of the architects—of the creators of such work? If architecture in its outward forms has not advanced by any revolutionary stages along the highway of progress, yet in the manner of construction she has and will develop exceedingly. Old Philbert de L'Orme, an architect of the French Renaissance, once said that an architect should have four eyes, four ears, and three hands, and if it was necessary then, what now? An architect nowadays is necessarily skilled in mechanics, several sciences, and in various arts connected with architecture. Now architecture differs in one essential quality: that while the latter is a matter of commonsence, which everyone understands, and therefore can appreciate, the former in its highest stages is based on appreciation of æsthetic quality, which the public can scarcely be expected to understand. The new century will be a utilitarian and scientific age essentially, and architects will have to adapt themselves more to the requirements of the time, and hold less to the antiquated ideals of the past centuries, if they are to capture and retain the public interest. We must be of the 20th century if we would succeed in it. Therein lies our great difficulty, prevalent in no other profession, for architecture is an art, science, and profession. In architecture we have the artistic requirements sadly hampered by the material needs, and above, dominating those, the professional qualifications requiring us, as men of business above all things, to protect our clients' interests. The question of architectural education, therefore, is an important one. The foundation of the Royal Institute of British Architects and the Architectural Association in this century, and the institution of professional examinations are merely the reflection of the spirit of the age, in which the public require to have some indication that the men they employ are capable, and, in fact, that they are qualified to practice their profession. This will undoubtedly lead to a compulsory registration for architects, when no one will be allowed to practice without a diploma. To the public it is a never-ending theme of amazement that anybody can call himself an architect. And truly it is quaint. We cause the men we direct on our buildings to be registered. We have our registered plumbers, our carpenters, bricklayers, joiners, plasterers, and masons, who have all served their apprenticeship, besides being technically educated, and yet anybody can call himself and practice as an architect. Let us think for a moment of the power for good or evil in an architect's hands, due to his knowledge or ignorance in matters connected with building, and then who can doubt but that this compulsory registration is bound to come? Opposition has always been forthcoming in these matters. In the law, in surgery, and in medicine, the same well-worn statements have been flung back to those who have advocated progress, and generally this opposition comes from the older men, the relics of a past age, who can see no good in change of any kind. The only real difficulty is the question of the possibility of examining in art, and, as far as the public goes, it would not matter if art were left out of the question, for in nine cases out of ten the public employ us to protect their interests, and not to provide them with artistic work, about which they know little and care less. The principal thing to remember is that the public expect us to be thoroughly qualified all round, to be directors and experts of all departments of building, and to possess the business qualifications for guarding their interests, which are usually associated with the profession of the law. If a profession or calling which is employed by the public is to continue to exist there must be confidence by the public; and how are the public to know with certainty the qualified from the unqualified, unless some official qualification is available? Again, a great part of the architect's ordinary practice consists in utilitarian work, which requires no artistic talent, but which does require great scientific and practical knowledge and business habits. We have elsewhere hinted that sanitation will be the guiding star of the next century, and in matters of drainage, and in everything connected with the hygiene of the house with which architects are concerned, and they will, no doubt, be properly registered to deal with such work. If persisted in, the present fine-art theory of architecture, held by a few eminent architects who have clients enough to support their fancy, will tend to the gradual absorption of legitimate architectural work by builders or big firms of decorators, who probably will employ a "tame" designer to put a frontal to their stock plans. In regard to the increasing complexity of our civilization, the number, extent, and intricacy of new types of constructions, it may also be expected that the tendency to specialize will develop itself, although the general practitioner will, of course, continue to hold his place, as in other learned professions. Such are a few of the thoughts which I have been able to put together, dealing with the future of architecture, and although they are far short of what I had hoped to produce, yet, in the time at my disposal, I have found it impossible to go more deeply into the subject, but hope that I may, at least, have made suggestions upon which a discussion may be profitable.

* From a paper read before the Birmingham Architectural Association, on Architecture of the Twentieth Century.

Draughtsmanship, says the London Building News, has been put before design or thought to a degree that has discouraged the practical and artistic minds in the profession: and we do not mean by this word skilful drawing or sketching, but the business of making and coloring perspective and other drawings of buildings by men who know little or nothing of construction.

THE SUMMER COTTAGE AND ITS FURNISHINGS.

Paper read by G. A. Reid, R.C.A., before the Ontario Association of Architects.

The question of the summer cottage may appear at first glance but a trivial one, one which might be set aside as a simple temporary shelter that the architect need not give more than passing consideration to. However, as we examine the matter it grows in import, and we find it is only a part of that group of problems the solution of which we hope will make possible a new life and nobler arts.

There can be no right consideration of any art which does not link its extremes together, which does not realize the dependence of the greater upon the lesser, and, while this is a truism in both art and life, the exigencies of our modern life have driven us to great extremes in our mode of living, producing conditions which huddle us too closely together in the cities, and separate us too much in the country, both of which are unnatural. Even the nomad races are social, carrying with them manners and customs which correspond to those of the races with fixed abodes. We are all idealists when it comes to building our homes, and whatever state of development we may be in we seek to beautify them even if they are barely habitable.

The summer cottage in the present state of the development of this new country can scarcely be considered by architects to be a practical issue in architecture.

The work of the architect under the conditions which obtain must of necessity be confined to narrow areas. His work will not pay unless he can go quickly from one building to another in the work of superintendence, and in these days of the books of 100 designs with estimates for $1.00 it is useless to consider the making of the design only. Moreover, no architect, I venture to say, but will agree that the right kind of work must be done largely in personal superintendence.

However, there are influences of an artistic sort working among us, which I believe will in time bring the minor erections more within the architects' field of activity. Perhaps even the stock design period which we have been in for some time may only be one of the indications of improvement.

Residence of Mr. G. A. Reid, R.C.A., Indian Road, Toronto.—Designed by Mr. Reid.

There are also influences of a material sort which I believe will combine to extend the influence and scope of the architect.

The main influence of the artistic sort may be said to be the development of the finer senses of the masses of the people through education and the consequent desire to surround the civil and domestic life with forms of art.

Those of the material sort are perhaps dependent on prosperity, for with assured stability both individual and general, more and more advantage may be taken of facilities for education through study and travel. The natural desire of every one is to have his own home, and if the forethought of the wise economist is added he considers the value in renting or selling in case of emergency. The great possibilities of new inventions and discoveries must also be counted upon to revolutionize our present conditions.

It seems, then, that it is just possible that the summer cottage may be a misnomer in the days to come, and that with new discoveries and inventions, and with rapid transit, the suburban home may become the country house, and the extremes to which we now swing in going into the wilds of nature for a period and living as artificial savages may no longer be felt necessary.

In any case though these speculations may be quite outside the realm of the practical at present, are not the possibilities very great, and quite well worth while contemplating?

Is it not a likely thing to see in the future with better conditions surrounding us, the architect designing with equal care the small and the large erection (I mean in respect to its qualities of fitness and appropriateness), and if competition were less strenuous, and the love of art and emulation were more, the impulses of the architect we can easily see that with the talent now here great things would result.

But in the matter of competition, without any change in the principle, I can see how the results may work out differently from what they do at present. As it is now, competition is short-sighted, and for the sake of getting a piece of work passed the contractor will resort to many devices and deceits, and to keep his job the workman will scamp, while the temptations to the architect are myriad. Human life is short and we are forgetful and forgiving, and while the friendly compact is a strong bond, and the wielding of the vote and influence has many aspects, when the day comes when the claims of art strike deep into the heart the judgment will be more inflexible, for who has known the true artist to be a man to use what is termed the "pull."

I say then that I can see how the character of competition may change, how the workman who is too true to his work will refuse to slight it after he knows what kind of work he is expected to do; how the contractor will find that the memory of the enlightened architect is long; how the architect can be more loyal to his art than to an ignorant client, and how the client himself may realize that his architect has an art to be true to, the contractor a duty and a name, and the workman a craft in which he can delight.

If at the same time social conditions were such that ostentation would be a breach of common good manners and honest ability was prized at its fullest worth the new art and architecture might be expected to appear.

In the meantime, which is certainly while we live, we will have to work along with very poor makeshifts in the arts. We will have to endure jealousies, imitations, falsities, and a lack of unity everywhere. And the first principle of art to put the right thing in the right place we are to see continually violated, and perhaps ourselves to become the victims of circumstance, for in that atmosphere there is a tendency to grow callous, and as we grow older our youthful ideas grow weaker one by one.

However, I would never admit that an artist or architect should be excused for getting so hardened in the use of makeshifts that he would cease to distinguish between that which was appropriate, and that which was inappropriate. Though there may be differences of opinion in details of the fit and the appropriate, there is unanimity in all the logical minded on general principles.

If we see a roof or a wall which suggests complete protection from rain and wind we derive a satisfaction, but our faculties are such that the first requirement when once satisfied demands the satisfaction of another and another, and never leaves off making demands. It is thus that the arts grow.

Growth in art, however, should not be mere addition of items but should in fact be the opposite, the refinement of parts and the elimination of the unnecessary. Thus the purest form of art may be a tendency towards economy. Certainly it is opposed to ostentation and pretence.

The union of the arts, which I believe ought to exist, can only be brought about, perhaps, when there is greater uniformity of education and general culture. This will serve to wipe out some of the causes of suspicion and jealousy which is the great obstacle to the broad development of the arts at present.

In a conversation which I had with an architect not long ago on the subject of mural decoration, while agreeing to the principle that walls should be decorated he said that architects could hardly be blamed for being jealous of mural decoration, as a picture placed on the wall of a building brought its author ten times more credit in proportion to the effort expended than that which went to the architect.

This, I believe, is about true, and it certainly is a deplorable thing that it is so, showing as it does the unbalanced state of true culture among us. Some phases of art are much exaggerated as to their true value, while other phases are wholly neglected. Some so-called art connoisseurs who fondly imagine that they are appreciating art are often merely valueing it in its aspect of the fashionable, curious or scarce. A picture or object may be al-

these and yet very poor art, but the point is that right appreciation should seek to intelligently discover merit in every form of art, and when not admiring it at least to respect it. This, however, can only be found when there is wide culture and consequent universality of thought.

Lack of unity in the arts and breadth of culture and appreciation brings in a whole train of anomalies in architecture as in all the arts.

In conclusion I wish to say that as an artist if I had no word to leave with you as a message I would not care to appear before you. I deem it an honor that I should be asked to address you and I hope I have made it appear so to you. But I prefer to consider that it it is an honor to the arts we represent that there should be an acknowledgement of interpendence, and while my effort has been to treat of a minor phase of architecture I regard the subject as a wide one involving the growth of the idea of the beautiful in the whole community, and the expression of it everywhere, from the simplest cottage in all its aspects of shape and setting, its furnishing and decoration, to the monumental building where we seek to stimulate ourselves to doing noble deeds by commemorating those that others have performed, and by holding up ideals of action and aspiration of beauty in form and color.

And whether we esteem architecture as the mother of all the arts from which she cannot be separated, or regard it not as an art but as that unifying principle which binds together the greater and the lesser arts it is all one in the interest of true art, the love of which should make for unity of purpose all the efforts of its votaries.

SYNOPSIS OF REMARKS ACCOMPANYING VIEWS SHOWN BY MR. REID PREVIOUS TO READING HIS PAPER.

Mr. Reid apologized that he should appear before the Association to show them some work of his own in the architectural line, but as the invitation to read a paper was accompanied with the suggestion that the subject should be "Summer Cottages," and as some of his architect friends in Toronto had come to know that his summer work was mostly given to the building of cottages at Onteora in the Catskill Mountains, he felt that it was only fair that he should show some of this work and give them the benefit of his experience. He said that there was, however, a difficulty to face in that it was hard not to make it appear a parade of his small efforts, and he would have found it much easier to talk on a subject which had to do with his own profession of painting more directly.

Mr. Reid then told of how in his boyhood he had been apprenticed to an architect and had some practical experience in building and that when he came to build his cottage at Onteora he set about to design and build it himself, and that the character of the cottage was admired by a settler in the colony who insisted, in spite of protests, that Mr. Reid should build a cottage for him on the same general lines. Several views of this cottage were put on the screen along with Mr. Reid's own cottage showing their points of similarity and difference. The essential points of the construction of various parts were shown, their adapation to site, etc., explained, and finally Mr. Reid said that though he had received compliments and admiration for this house from many known people, some of them noted New York architects, he felt more satisfaction in the fact that he had been commissioned to paint a decoration round the upper part of the high living room, for however much he liked to build he preferred to paint still more.

A number of views of cottages were thrown on the screen among them were some of the cottages built last summer for Miss Maude Adams, the actress, who made such a success of the role of Babbie in the "Little Minister," and also the little stone church, an interior view of which showed Mr. Reid's decoration of adoring angels.

In an apologetic way Mr. Reid said he had to confess to about twenty erections, numerous alterations, and over 100 pieces of furniture, some of the latter being shown in the photographs. A general description of the colony was given, the artistic and literary pursuits of its inhabitants, etc., and some general views were shown. The last slide shown on the screen was a view of Mr. Reid's house just built in Toronto from his own designs, and which he remarked had helped to get him into the dilemma of having to show his amateur performances to architects.

A prize of $500, to be annually awarded irrespective of age or sex to the best picture by an American artist residing in the United States, has been established at the Society of American Artists by Mr. Andrew Carnegie.

PERSONAL.

Messrs. Eden Smith and J. P. Hynes, architects, have removed from the Canada Life Building to new and more commodious offices at No. 32 Adelaide Street East, Toronto.

Mr. C. H. Rust, City Engineer of Toronto, has recently returned from Europe, where he spent some time in studying methods of sewage disposal and other problems in municipal engineering.

Mr.F. S. Baker, F.R.I.B.A., of Toronto, was recently bereaved of his father, who was drowned by falling into an open well at Utterson, Muskoka. The late Mr. Baker, who was 72 years of age, was a well-known and much respected lumberman.

Mr. Acilde Chausee, Architect and City Building Inspector of Montreal, has received notification of his admission on Jan. 10th as a corresponding member of the Societe Central des Architectes Francais. The notification was accompanied by a diploma in bronze of artistic design.

A grateful tribute to one who did much to beautify American cities has been paid to his memory by the Park Commission of Boston. It has joined Leverett and Jamaica parks and given the name of Olmsted Park to the entire area. Frederick Law Olmsted put the stamp of his genius on most of the notable parks of the country, and it is gratifying to learn that his name will hereafter be associated with a work of this sort.—Engineering Record.

Prof. Loudon, President of Toronto University, and Mr. C. H. C. Wright, Lecturer in Architecture at the School of Practical Science were recently tendered a complimentary dinner by the Madawaska Club. This organization, of which Messrs. Louden and Wright have been active members, is composed of the faculty and graduates of the university. The club have a summer rendezvous on the Madawaska River, in the Georgian Bay district.

Mr. H. C. Symmes, a well-known engineer and contractor died at his home at Drummondville, Ont., on the 9th inst., of congestion of the lungs. Mr. Symmes was a graduate of Harvard University. In his early days he was connected with the engineering staff of the Great Western Railway. Subsequently he became senior member of the firm of Symmes & Mitchell, and carried out many important contracts in connection with the construction of the Welland and St. Lawrence Canals, Toronto Water Works, the Cantilever Bridge at Niagara Falls, the Chignecto Ship Railway, etc.

THE NEW TORONTO HOTEL.

THE new Toronto hotel, an illustration of which appears in this issue, will cover an area of 164 x 197 feet, and will be six storeys high. It will be constructed of brick and stone with terra-cotta trimmings, and will be made absolutely fireproof. The main hall will be finished in marble and oak, the entrance in Cuban mahogany and marble, the cafe in oak and marble, the restaurant in ivory and gold, and the Rathskeller in oak and marble. The bedrooms will have cement floors.

AN IMPORTANT COMPETITION.

THE West Australian Government is inviting competitive designs for new Houses of Parliament, to cost $100,000. Three premiums are offered, viz., £500, £200 and £100 for the first, second and third designs. The designs are to be delivered on April 16th, 1901, and the competition is to be open to all.

The name of the Hamilton Art School has been changed to "The Hamilton School of Art, Design and Technology."

An Ottawa despatch states that the statue of the Queen ordered by the Dominion Government some time ago will be placed in position on the main walk to the Parliament buildings in front of the main entrance. The monument of Hon. Alexander Mackenzie will be placed on the lawn near the library.

The Society of Engineering and Applied Science was recently organized at London, Ont. The following are the officers elect: President, Prof. Bowman; vice-president, F. W. Merchant, M.A.; secretary, F. W. Farncombe, C. E.; treasurer, R. Kirkpatrick; Organization committee, Messrs. Merchant, Hunt, Mitchell, Leonard, Bowman, Henry, Sifton, Campbell, and A. W. Whyte.

The Ontario Society of Artists have elected the following officers: Hon. Pres., Hon. G. W. Allan; Pres., G. A. Reid; Vice-Pres. and Treas., C. M. Manly; Sec'y, R. F. Gagen; Executive Council, Messrs. F. M. Knowles, F. S. Challener, Laura Muntz, J. W. L. Forster, G. Hahn, W. D. Blatchly, and F. M. Bell-Smith; Industrial Exhibition representatives, F. McG. Knowles and E. Wyly Grier.

BY THE WAY.

THE Toronto Athletic Club building recently purchased by the city council of Toronto has been remodelled under the direction of Mr. A. F. Wickson to meet the requirements of the Toronto Technical School. On the first floor are the classes in modelling, architectural drawing and building construction, industrial art and freehand drawing.

× × ×

SEVERAL informal luncheons have lately been held by the architects and engineers of Toronto in the new rooms which have been fitted up for the use of these bodies at No. 94 King Street West. The popularity of the idea is attested by the good attendance. The majority of professional and business men lunch down town, and there is every reason why they should once a month or oftener meet in this way, enjoy a social chat and better their acquaintance.

× × ×

A GENTLEMAN who had an office in the Board of Trade Building, Montreal, writes that when the vault was opened after the fire which destroyed the building, the books and papers which he had placed therein for safe-keeping, were found to have been reduced to dust. The subject of vault construction is one to which greater attention should be given. Unless a vault be constructed in such a way as to be absolutely proof against fire, it is worse than useless, as persons are likely to entrust to its false security their confidence and valuables.

THE announcement that it is the intention of the American Institute of architects to hold its next convention in Buffalo during the Pan-American Exhibition, leads me to suggest that the Ontario Association of Architects and the Toronto Architectural Eighteen Club might organize an excursion to the Exhibition which should prove a pleasant and profitable outing. It may be regarded as a foregone conclusion that with such an attractive and instructive display of architecture so near at hand every architect in western Ontario will determine to visit Buffalo next summer. Why then, should they not decide to go as body and thus be able to compare notes?

× × ×

THE tower of Bond Street Congregational Church, Toronto, has recently been an object of curiosity to architects and the public. The tower is built of grey stone which has grown dark and soft in color under the influence of the weather. At the south west corner is a pinnacle supporting a metal finial. Until recently this pinnacle corresponded in color with, and was generally supposed to be constructed of the same stone as the tower. The enterprising painter who recently "touched up" the wood work on the exterior of the church painted the pinnacle a glaring yellow, thereby proclaiming it to be of wood, and giving it the appearance of something which does not belong to the tower, but has been by accident "stuck on."

× × ×

I AM sorry to notice the manner in which the subject of a memorial to our late Queen is being dealt with in Toronto. Instead of uniting upon a well considered scheme, the citizens are being asked to support this, that and the other proposal. One of the latest suggestions is that a grand concert organ be purchased by subscription for the Massey Music Hall. The musical organization of which the author of the suggestion is the conductor forthwith committed itself to the scheme, by voting $500. If when the matter comes to be properly considered by all classes of the citizens, some other form of memorial should be decided upon, the organization referred to will probably withdraw its subscription. The citizens should hold themselves perfectly free until the subject has received proper discussion and consideration. Then let individual opinions and preferences be put aside in favor of what in the judgment of the majority should be done. If effort and money are wasted in half a dozen directions, nothing worthy of the occasion will be accomplished.

THE Architectural Review, of Boston contains the following kindly reference to this Journal: The CANADIAN ARCHITECT AND BUILDER appears in a new and vastly improved form. The plates are better from a technical standpoint and the subjects illustrated are also of a higher order. In his review of the work of the century, the editor has analayzed admirably the events that have occurred, and his forecast of the possible future is no less intelligent. He declares that American architecture at present is French, very French, and few would be disposed to disagree with him. On the other hand, we are afraid still fewer would admit that he was right when he says: "It is a great question whether the real American architecture is not quietly developing elsewhere under the hands of Mr. Wilson Eyre and others. The Philadelphia school seems to have elements of true greatness in it". To be sure it seems to us that in this he is absolutely correct, but we were hardly disposed to believe until we saw the fact noted in a Canadian magazine that the admirable work of those who refuse to bend the knee to the dicta of the graduates of the French School of Fine Arts had impressed itself sufficiently upon the public mind to make possible a general recognition of its qualities. This testimony from an "extra territorial" source is profoundly gratifying. We reproduce one of the illustrations from this number. A view of the rear portion of the "Bible Training School," Toronto, by Messrs. Burke & Horwood, to our minds a much better piece of architectural design than the more ambitious front.

REFERRING to the steadily growing fire loss in cities and the claim of the insurance companies that they are unable to realize profits at existing rates, the American Architect says: "The high department stores which give our conscientious building inspectors so much anxiety might be transformed in a week if the underwriters themselves would have the resolution to make the premium rates on them proportionate to the risk; but the temptation of a large line of insurance is too much for them to resist, and by keeping down rates on dangerous accumulations of goods, trusting to be able to make up their losses at the expense of the smaller and safer risks, they encourage the methods of building which they rail at architects for not suppressing. If the underwriters really wish to "reduce the fire-waste" in our cities the way to accomplish that end is to second heartily the building inspectors in their efforts to have the undivided space in mercantile buildings restricted by law within prudent limits; to use their influence for the repeal of the customs duties on structural iron, and to urge, in the several States, the passage of laws restoring neighborhood liability in case of fire. When these three objects are accomplished, it will not be long before great fire losses are quite as rare in our cities as they are in Paris or Vienna, and the underwriters, who alone have the influence necessary for bringing them about, will be prosperous and happy again, at the same time that they will have conferred upon their fellow-citizens an inestimable benefit."

PORCH OF CANADA COMPANY'S BUILDING, KING STREET EAST, TORONTO—(THE OLDEST BRICK BUILDING IN TORONTO)—NOW IN PROCESS OF DEMOLITION.

EXAMINATIONS FOR ARCHITECTS.*

By W. Cooper.

The training of an architect's pupil, if carried out in the orthodox style, is somewhat as follows, varying slightly according to circumstances :

On entering the office he practises office routine, such as copying specifications, quantities, and builder's accounts, tracing or copying drawings made by the draughtmen of the office, and in spare time copying examples of well-known works, measuring up old buildings, studying building construction (and sometimes geometry and other perspective) reading the history of architecture, and endeavouring to learn dates relating to the same ; occasionally he will attend art classes and science lectures in connection with the School of Science and Art in the provinces, or if in London, he will attend King's College, the Architectural Association classes, or other technical classes, and various private preparation classes.

Thus, if the student wishes to excel in the examinations instituted all over the world for the advance of his art, he must work diligently upon the works of other men, both in buildings and in writings, leaving no time for improving himself in any original ideas that he may be possessed of. He is induced to enter a competition for a scholarship or for a building ; and how well he knows that if he does not adopt the particular style in fashion, he stands no chance of success. For instance, what assessor will now look at Gothic work ?

It is needless to say that such a process of education stamps out for all time any chance of the student working in an original way ; because usually his time for working out original problems has passed when he commences working in earnest professionally ; yet this is the course of study which must be adopted if a man wishes to pass an examination to qualify as a member of any society of architects of standing. It is essential that an architect should have an artistic mind ; he should also be a constructor, he should be trained in business matters, he should have a very thorough practical knowledge of materials and their uses, and be up to date in sanitary matters.

In design absolute freedom should be allowed to the candidates. Style should be ignored, and many marks awarded for good proportion and consistent originality ; this would save some very precious time in preparation, and anxious and worrying months comparing differences of style, periods of architecture, and details of ornament relating to the same ; it would also induce a freedom not yet attained by latter-day architects. Study of former examples is well in its way; but it should be confined to the archæologist. Why go back ? If progress is required the motto must be "Forward."

Some will say, "Who is to judge the artistic merits of the design, or the good proportion of the features composing it?" The reply to this is, "Who shall judge the value of a picture?" or any other work of art, such as the grouping and finishing of a design in sculpture.

Very few marks should be given for draughtsmanship. It is a great tax upon some art men to make finished geometrical drawings, and this has the effect of cramping the hand and injuring the eye for drawing freely. A good knowledge of freehand drawing, shading, and perspective is imperative ; sufficient value is not given to these subjects, although they are all important to the art-architect.

Unfortunately the gift of art and science is not usually very fully developed in one brain ; consequently our most artistic men are bad constructors, and good constructors are invariably bad designers. Time can well be saved by requiring only a knowledge of the books in which to find formulæ for calculating strains and stresses, and other things (which are now required to be committed to memory), and how to work them out. The candidate should therefore be allowed to have the books of reference, such as architects have in their offices, but the questions should be such that the test of the study of the books is very thorough, so far as the means of finding out matter necessary to correct construction is concerned.

The anatomy of the building must be known, for as the sculptor and painter is better qualified by knowledge of the anatomy of the subject he carves or paints, so an architect must be more proficient the more he knows of the general principles of construction. The examinations in this should be very searching. Usually there is too much theory and not enough practical knowledge required of the candidate. Foundations, and how to deal with any foundations upon which a structure is to be built, should be one of the compulsory questions.

In this paper the candidate should show a knowledge of the names and addresses of well-known experts and testers of all classes of building materials, how all kinds of building materials are employed, and the reason why they are used for particular purposes ; he should also know the colour and distinguishing features of the various stones and woods. Some rough-and-ready pratical tests of the materials, such as bricks, stone, cements, lime, timber, and artificial preparations should be required, but most important of all, a thorough acquaintance, by sight, with the actual materials, samples of which should be in the examination-room. To the artistic mind, committing matter to memory is usually tedious and aggravating to a degree, but to remember by sight is comparatively easy.

The Contract.—A copy of this should be placed before the candidate and it should be required of him to explain any portions of it. What is the use of committing it to memory, as is required by most examining bodies ?

Prices.—A schedule of prices should be given, upon which to base the estimate of works or of the contractor's bill of extras. Values vary so frequently, and rise and fall so rapidly, they also vary in different centres so much that it is impossible to have a thorough knowledge of them at any time.

Quantities.—A certain knowledge of quantities is necessary, both in the method of taking them off, abstracting and billing, but few marks should be given for this, because an architect is not necessarily a quantity surveyor, but it is required of an architect to be able to check measurements and to measure his own work.

Land Surveying and Levelling.—This is wanted in a limited degree, and no examination is complete without questions upon it, because every architect who has to live by his profession, with a small practice, has problems in land measuring, and it is necessary to his success that he should know how to do it, at any rate until he can afford to keep or employ a land surveyor to set out the plan and levels of the land he proposes to develop.

Specifications.—A thorough knowledge of specifications is essential, and the candidate should be required to write a specification governing every part of his design, with the assistance of a skeleton specification to work upon.

Sanitary.—The general laws laid down by sanitary experts should be known by memory, both for a building in the country and in a town ; he should know how to test drains and to check the deception practised by contractors. For weights of pipe, etc., books of reference might be allowed.

Decoration.—Without the qualification to blend colour, many an otherwise good building would be ruined. Decoration should have strict attention and rigid examination.

Time for the Examination.—Two weeks, at least, is necessary to do justice to the subject. Some are much slower in their work than others ; ample time should therefore be given, so that the slow and thorough should have the same opportunity as the quick.

I have endeavoured to show by this paper that I would expunge from the examinations all unnecessary questions, such as : "Where does olive oil come from?"; "Who was Xenophon?"; geography, languages (except English), mathematics (beyond that portion required in an architect's practice), dilapidation, chemistry of materials, history, and all other subjects unnecessary to the uplifting of architecture in the true sense of the work.

We are living in an age of construction unlike any the world has ever before experienced. I mean steel construction ; yet there has not been a successful attempt to apply it architecturally. Why is it so? Because architects of the present generation are trained to slavishly copy and study the works of architects in stone and wood. Under the present system of tests, the man who has the best memory holds the best position in the examination. It should be the man who answers the most practical questions best should be given the first place.

*A paper read before the Society of Architects, London, on December 18th, 1900.

Branch Office of the CANADIAN ARCHITECT AND BUILDER, Imperial Building.

MONTREAL, March 15th, 1901.

THE SPRING EXHIBITION.

The annual exhibition of pictures at the Art Association's galleries was opened on Friday, March 8th, and will remain on view until the 23rd inst. As usual there was not much interest shown in the architectural drawings, but then we regret to say there was little in which to take interest Outside of Mr. W.S. Maxwell's drawing of a "Salle des Fetes" made by him during his recent stay in Paris in the "Beaux Arts" style of rendering there was not much of note, and in point of numbers the exhibition was woefully wanting. Mr. A. T. Taylor exhibited a water color sketch of the Merchant's Bank building for Winnipeg and a sketch of a small bank building at Sydney, C. B. The latter is a type of building which should be largely in demand in Canada as there will, no doubt, be several small towns cropping up in the next ten years desiring buildings of this class. Why do not persons interested in the arts and crafts exhibit drawings and sketches of decerations and interiors, ornamental grills, and other iron work, lamps, etc., and such work as is to be seen in the pages of the Studio? Surely there is a growing demand for these things in Montreal, and the ladies who are generally interested in interior decoration have a field open here for them. The exhibition of china painting certainly seems to have called forth the energies of the ladies, and we give them hearty praise for the display which does them credit.

THE BOARD OF TRADE FIRE.

The recent disastrous fire which demolished the Board of Trade, besides several other buildings in that district, has occurred since our last letter. The lessons to be learnt therefrom were chiefly those which ought to have been learnt long ago, viz., the lack of men and apparatus in the fire brigade ; the great drawback received from the net-work of telephone and electric wires in a congested district ; the fact that a fire wall is about the only thing that will stop a large conflagration, and the necessity ot better, that is, fireproof buildings, in the centre of a large city. The improvement of the fire brigade is out of our province, except when we are commissioned to build a new fire station, and we would like to urge here that the city council be called upon by an amalgamation of the art interests of the city to insist upon either competitive plans or a competent local architect being employed for any new fire stations that may be required, and are evidently badly needed according to the report made recently by Mr. Howe to the Canadian Fire Underwriters.

Concerning the numerous wires we would like to add our voice to that of others in recommending that the city council enforce the various companies in the congested district, that is where the insurance companies have raised the rates, to place their wires in a large conduit underground. If need be this could surely be done by an outside company and space rented out and thereby make a good precuniary profit to themselves, and at the same time do the citizens as a whole a lasting benefit. There is no doubt that the overhead wires are a menace to the public at all times, while in the event of heavy storms or a fire they are a danger that is too great to be trifled with and a great cause of expense to the companies, that one would imagine for their own sakes any attempt to force them to place them underground would not be met with any very strong opposition.

From an architect's standpoint there is the further disadvantage in the ill effects they have on the vista down some of the chief streets of this city with whole rows of poles carrying their network of wires.

Montreal is gradually growing to be one of the large cities of this continent and in which fierce commercial competition is being met on all sides, and merchants have now to compete against merchants from all over the world. They can, therefore, ill afford a raise in the insurance rates, as they have by force of circumstances to scrutinize every item of expense. Merchants can also, as a rule, ill afford to have a fire, as an interruption of their business generally means their customers going over to a competitor. They should, therefore, look beyond the first cost of a building and see that they are protected somewhat against loss by fire. Do not blame the insurance companies for the raise in the rates, but blame yourselves, ye who build such firetraps as are to be seen throughout the city. Can one blame the insurance men when there are buildings in the centre of a congested district with absolutely no protection whatever against fire—no sprinklers, no standpipe with hose connections,—or even if there is a standpipe a hose without a nozzle, as can be seen in one of the largest office buildings in this city. Such things should not be allowed, and if persons who own such property have not more thought for the lives and property of their tenants there should be some law which would enforce them to do so.

THE LICENSING OF ARCHITECTS.

The question of the value of licensing architects should be of vital importance to all those concerned in the welfare of the profession in the Province of Quebec. As is well known "no person" in this province can take " or make use of the name or title of architect, either simply or in connection with any other word, name, title or designation, giving it to be understood that he is an architect under this act unless he is registered under this act as a member of the said association." Any person since 1898 using the word "architect" in the Province of Quebec, unless registered, is subject to a fine not exceeding twenty-five dollars ($25.00) for the first offence andnot exceeding one hundred dollars ($100) for every subsequent offence.

In the State of Illinois, the only state at present with a license law in the United States, all architects after passing the final examination are given a seal with their name and address impressed thereon with which all plans emanating from their office have to be stamped ; and further-more, no building permit will be issued except on plans so stamped with the seal of a licensed architect. This appears to us to be carrying the thing too far, as no man should be hindered from erecting buildings from plans of his own, or without any plans for that matter if he so desire, but he should be restrained from employing another person to make plans for him who is not a licensed architect. A man can doctor himself or plead his own case in court, but in neither case can he practise medicine or law without a license. In New York State they are now discussing the pros. and cons. of licensing architects, as a bill is before the legislature. There seems to be opposition both from some of the architects and the general public, and the outcome seems doubtful. The chief points usually brought to bear against a bill for licensing architects is the undoubted impossibility of testing the artistic merits of a candidate by an examination. This is almost universally acknowledged to be a difficulty, but it is possible to test whether he knows the rules governing both the artistic and the scientific sides of his profession. Any person practising architecture, which is now generally acknowledged to be one of the learned professions, should be able to pass a general examination equal to the standard required by the medical or legal fraternity. He should further-more, in a final examination, be able to pass in the following subjects : Perspective and free hand drawing ; shades and shadows ; mechanics ; elementary geology and botany ; hygine ; modelling ; building construction and materials ; pen and ink drawing and wash work ; colour and decoration ; history of art and architecture ; design ; specifications and contracts ; architectural jurisprudence.

Of course a candidate might pass in all these subjects very creditably and yet not make a "great" architect, but at least one would know that he was in a position to build safely and correctly and would not contravene all rules of good taste. This is as much as can be said of any profession, and there will and almust be many grades in every calling. There is now undoubtedly a growing tendency on the part of the general public to appreciate intelligently the difference between good and bad in architecture, and it is the duty of all architects to keep out of the profession all those who hinder its progress.

Now that the Quebec Association has received its charter and has had time to get down to work, it is high time that something should be done to teach students, as this responsibility has by this charter been thrown upon the shoulders of the Association. There is at the present time no attempt to do anything to further the interest taken by students or to place before them the opportunities for serious study. It is the earnest desire of many to see some form of study in the way of lectures, modelling classes, etc., and also monthly competitions started by the Association, and we trust if too late for this season, there will not be another year pass without some effort by all the members to see that this blot does not remain on our work. Surely the Association could join the American League and so obtain the circuit drawings as was recently done by the Toronto Architectural Eighteen Club. "The Brickbuilder" recently commented on that exhibition by saying, "The first Architectural exhibition of any pretensions ever held in Canada occurred in Toronto, January 26th to February 9th, under the auspices of the Toronto Architectural Club, and from all points of view it was voted a success and heralded as a permanent entry on the part of the architects of Canada into the progressive movement for the advancement of architecture and municipal arts." Let not this progressive movement stop until it at least includes Montreal, and it is a splendid opportunity for both members and students to compare their work with that which is being done by others, and there is nothing like a healthy comparison of work to make and stimulate an interest in one's own. We would like to suggest that the Association should offer prizes for monthly competition during the winter months, the prizes to be given on a vote of members, as is done in the T Square Club. Possibly some of the honorary members might be glad to offer a prize or medals, and I fancy one or two at least would certainly come forward if asked. Surely the days ought to be past when men were afraid lest some one else should steal their ideas and so frustrate any attempt at co-operation or "esprit de corps."

SCHEDULE OF CHARGES OF THE P. Q. A. A.

An order-in-Council was passed by the Quebec Legislature on the 8th inst., legalizing the schedule of charges of the Province of Quebec Association of Architects, as follows:

No. 1—The architect bases his professional charges upon the entire cost to the owner of the building when completed, including all the fixtures necessary to render it fit for occupation, and is entitled to extra compensation for furniture and other articles designed or purchased by the architect.

No. 2—If any of the material or work used in the construction of the building be already upon the ground or come into possession of the owner without expense to him, the value of said material or work is to be added to the sum actually expended upon the building before the architect's commission is computed.

No. 3—Travelling expenses are to be paid by the client.

No. 4—The charge per day which may be made by an architect will depend upon his professional standing, but the minimum charge will be $10 per day.

No. 5—In all cases where an architect is subpoenaed professionally as a witness in court, he shall be entitled to a fee of $4 per day of attendance.

No. 6—Drawings and specifications, as instruments of service, are the property of the architect.

No. 7—In consideration of the charges mentioned hereafter, the architect will be held to furnish a series of drawings and specifications as originals, and copies of these same drawings and specifications for the use of the contractors, but it will be well understood that all the originals and copies must be returned to the architect when the work will have been completed.

No. 8—For professional services in connection with all buildings, comprising preliminary studies, complete plans, specifications, details and superintendence, the architect will be entitled to a commission on the total cost of the building when completed, in the following proportion:—

On all classes of buildings costing less than $50,000, 5 per cent.

On all classes of buildings costing from $50,000 to $150,000, 4 per cent.

On all classes of buildings costing more than $150,000, 3 per cent.

No. 9—Partial charges, in the case of subdivision or discontinuation of the work, will be as follows:—

For preliminary studies (sketches), one-fifth (1/5) of the above charges:

For complete plans and specifications, including the preliminary studies, one-half of the above charges (½).

For details, one-fifth (1/5) of the above charges.

For superintendence of the works, when drawings are not furnished, two and one-half per cent. (2½) on the cost of the works.

No. 10—In exceptional cases, for all works of alterations or of restoration, the architect will be entitled to a commission of seven and one-half per cent. (7½) of the cost of the work.

No. 11—For all other work (also exceptional) in which the expenditure is mainly for artistic workmanship, viz.: For monumental work, fittings and furniture, and for decorative work, stained glass and such like; the architect will be entitled to a commission of seven and one-half per cent. (7½) on the total cost of the work.

No. 12—For valuations of property requiring measurements and detailed estimates, where the value will not exceed $5,000, one and one-half per cent. (1½). Where the value exceeds $5,000, the commission will be one and one-half per cent. (1½) on the first. $5,000, and one per cent. on the remainder (1).

No. 13—In case the owner of the building or the contractor should require the services of the architect to prepare quantities or for measurement of the work done or to be done, such services will be paid (outside of the regular commission) at the rate of two per cent. (2) on the valuation of the cost of the work.

NOTES.

On severing a connection covering seventeen years with the firm of Millar Bros. & Toms, Montreal, Mr. A. M. Elliott, was presented with a gold watch by his fellow employees and with a chain and locket by Mr. J. D. Millar on behalf of the firm.

Another competitor in the brick market has recently been heard from, viz., "the Drury brick" from Essex county, Vermont. It stands a good absorption test but is smaller than most bricks made in Montreal and requires about 23 bricks to the cubic foot instead of from usually 20 to 21 Montreal bricks.

The death of Mr. Jacobi, an artist well-known in Montreal, and a former president of the Royal Canadian Academy, removes one of the older artists in Canada. He was born in February, 1812, at Konigsberry in Prussia and came to Canada in 1860, where he remained, with the exception of a short absence, until shortly before his death, which occurred in Dakota.

The result of the recent examinations for the Architectural Association has just been posted: H. C. Stone, of Montreal, and Pierre Levesque, of Quebec, are granted licenses to practise as architects in the province, and the following passed the preliminary examinations: Sholto Smith, of Montreal, J. J. T. Donelly, E. P. Raymond and Charles A. Lemay, all of Quebec.

Mr. Dore, sanitary engineer, Montreal, examined during the month of January 17 building plans, visited 147 homes where plumbing required inspection, issued 16 notices about improper workmanship, and issued four plumbers' certificates. He complains that many plumbers are using lighter material than the by-law calls for.

Mr. J. O. Marchand, who enjoys the distinction of being the only Canadian student of architecture at the Ecole des Beaux Arts, at Paris, has recently resumed his studies after having paid a brief visit to his parents in this city. Mr. Marchand expects to obtain his final diploma in June, after which he will begin the practice of his profession in Montreal.

Mr. Charles Philippe Hebert, the Canadian sculptor, has been made a Knight of the Legion of Honor by the French Government in recognition of his services to art in France and Canada. The Maisonneuve monument in this city, a group of historical figures on the facade and in front of the Legislative Buildings at Quebec, and the statues of Sir George E. Cartier and Sir John A. Macdonald, at Ottawa, are among his most important works.

It is announced that from May 1st until June 30th classes in drawing, painting and modelling, open to men and women students, will be held in the rooms of the Architectural Department of McGill, under the direction of Prof. Henry F. Armstrong. The rooms will be open on week days from 10 a.m to 5 p.m. Students may pursue their studies in one or more of the subjects continuously every day. Teaching and criticism will be given daily during the above hours, except on Saturdays. The subjects taught will be:—Freehand drawing, in lead pencil and in charcoal, for students preparing for, or engaged in, any branch of art work, and in lead pencil, for engineering and other science students; oil painting and water color painting; and modelling in clay and casting in plaster.

Prof. W. R. Butler read some abstracts before the Canadian Society of Civil Engineers on February 28th from two papers recently given before the Liverpool Engineering Society, termed "The Characteristics and Qualities of Portland Cement" by Mr. P. A. H. Shaw, and "Experiments on the Artificial Acceleration of the Setting of Portland Cement," by Mr. F. E. Priest. In the first paper the importance of fine grinding was particularly emphasized and in speaking of the value of weight as a criterion of quality the author showed the variations in the weight of samples of the same cement at different ages as follows:

At age of one day,	weight	117	lbs.	per	bushel.
" 1 month	"	113	"	"	
" 2 months	"	108	"	"	
" 12 months	"	103	"	"	

And as examples of variation in weight due to fineness in grinding the following were quoted:

10%	residue on	80	mesh sieve	weighed	110	lbs. per bushel.
20%	"	80	"	"	116	" "
25%	"	80	"	"	121	" "
35%	"	80	"	"	123	" "

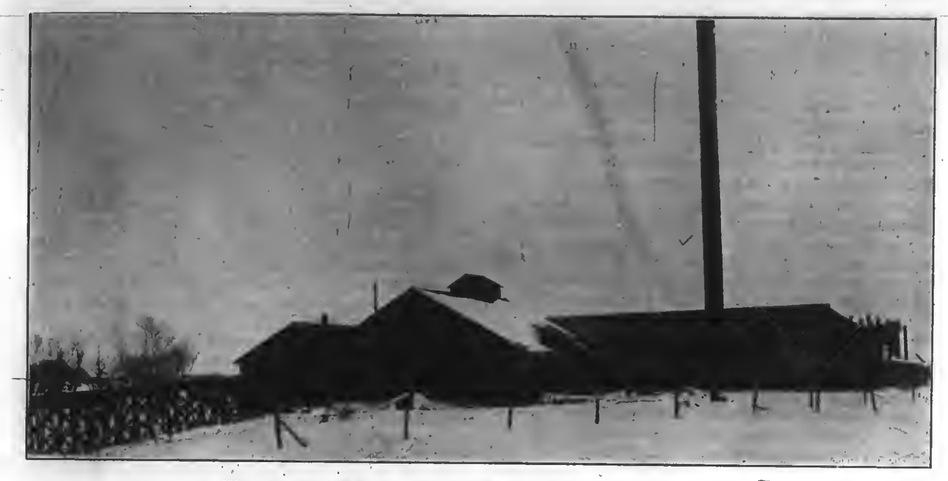
The above figures should be of interest to architects as well as engineers. J. R. G.

MANUFACTURES AND MATERIALS

THE MARITIME CLAY WORKS COMPANY, PUGWASH, N. S.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

During the past two years a new and modern brick making plant has been in process of construction in Pugwash, N. S.



WORKS OF THE MARITIME CLAY WORKS COMPANY, PUGWASH, N. S.

This has now been completed and for some time has been turning out heavy shipments. It is unnoubtedly the largest in the Maritime Provinces and is thoroughly modern in every respect ranking among the finest in the Dominion.

The natural advantages of the site were good and the clay and sand required were in close proximity, of the best quality and inexhaustible. There were old clay works here forty years ago and some of the old buildings still stand, but they were quite small.

Robert Brownell, of Truro, was one of the early promoters of this concern. The late Hon, Mr. Dickie, of Amherst, saw the advantages of the site and took up the work, furnishing until his death much of the means for construction. After that event the present members of the firm bought out the stock and plant and have since made great changes and improvements to the plant.

The present members of the company, incorporated in 1898, are Alonzo Smith and R. M. McDonald, both natives of Pugwash. They are both good business men and are opening up the business as thoroughly as it can be done.

The plant is located immediately across the river from Pugwash and is connected with the clay beds, one and a half miles distant, by a railway which is the firm's property.

The clay beds form a solid bank, twenty-five feet high and about a mile in length. The quality is extra good, some experts say among the best they have ever seen, and there is not a stone to be found in it.

The railway was constructed last summer and is fitted with a locomotive and good rolling stock. It terminates in the factory over a high trestle so that cars may be run up over the machinery and easily dumped. The sand is obtained from the harbor shore, a few hundred feet from the mill and is of clear and even quality in inexhaustible quantities.

The buildings and yards cover a great area and are laid out as conveniently as possible. The buildings are all of brick, and are covered with heavy galvanized iron roofs. The main building is of size about 75 x 100, including the shed for clay, etc. The engine and boiler rooms are attached, of a size 30 x 24. The engine is of 80 h. p., and there are three boilers, two of 75 h. p. each and one of 50.

There is some large and powerful machinery in the machinery building. All his apparatus came from Bucyrus, Ohio, and is of the latest pattern. The wire cutting machinery has a capacity of 35,000 bricks per day. The dry press machine has a capacity of 20,000 a day, though it is not generally operated at that speed. The dry house is about 100 x 40 of 6 chambers and with a capacity of 40,000 per 24 hours. The exhaust steam from the engines goes into the dry house. A fan which will be put in this winter will increase the capacity to about 50,000.

WORKS OF THE MARITIME CLAY WORKS COMPANY, PUGWASH, N. S.

The old wooden kilns at first used have been done away with. The plan of the new continuous kiln were obtained in California and is the only one of the kind in the Maritime Provinces. The size is 164 x 52, and its capacity for the 18 days required for a burning is 450,000.

The daily capacity of this kiln is just about 35,000. Its construction requires care and skill and its cost was great, but is well justified by results. The mouths or doors to the chambers are closed and cement sealed during burning. The contents of a chamber may be removed and the chamber be filled again while the rest of the chambers are in full heat. Coal is used, and this fuel, in very fine condition, is fed through many small intakes overhead, sifting down through the bricks to the bottom. There are 1,200 ormore of these feeding holes, ot a diameter of about 4 in., each provided with a cover. This new kiln was just started last September.

As much as 35,000 stock and 10,000 pressed brick have been turned out in a day. All future orders can be filled up to 30,000 bricks per day.

A small artificial kiln stands near the continuous one, which though only of about 12 feet diameter and 10 feet high, has a capacity of 17,000.

In the spring a new building 20 x 40 is to be constructed to contain burned and dry bricks. Then all parts of the work and stock will be fully under cover. New tracks will be laid to the wharves and other improvements carried out.

The large chimney belonging to the works is 140 feet high and over 6 feet in inside diameter.

About 40 men are now employed in the works. So much machinery is now used the old number has been much lessened.

Altogether the plant has cost about $62,000 including from $4,000 to $5,000 for site and about $3,000 for rolling stock.

Large shipments have been made to Sydney to the Dominion Coal Co., the Dominion Iron and Steel Co., N. S. Steel Co. and Rhodes, Curry & Co., Cumberland Coal Co. (160,000 M). Orders are in hand for a quarter of a million to Sydney, about 1,000,000 to Prince Edward Island and half a million to Pictou county. A considerable quantity has been shipped to New Brunswick, including an order of 20,000 to Kingston.

At present the bricks are taken over the river to the railway a distance of some few hundred yards in lighters and tugs, but it is the intention to put in a wire cable carrying system which will solve this difficulty.

More business has been found than was anticipated, and the operation of the new plant is in every way successful.

THE COMPOSITION OF SOME CANADIAN LIMESTONES.

(A) For Calcium Carbide; (B) For Chemical Wood Pulp; (C) For Portland Cement.

BY J. T. DONALD, M.A., Montreal.

The rapid development of industries in which lime or limestone is a raw material has given a new interest to this common mineral. The term limestone, however, as generally used includes any rock in which carbonate of lime is the predominant ingredient. This of course gives a wide range of composition. The ideal limestone is pure calcium carbonate containing 56% of lime and 44% of carbon dioxide.

The conditions under which beds of limestone have been deposited were such that it is scarcely possible to find them fully up to our ideal in degree of purity.

Being a sedimentary rock, we usually find limestone containing more or less siliceous matter, either as silica or as silicates. The amount of siliceous matter may vary from a few tenths of one per cent., up to even forty or fifty per cent.; in which latter case it is a question whether we should consider we have a sandy limestone or a calcareous sandstone.

But again, in nature we usually find that carbonate of lime is associated with carbonate of magnesia; indeed it is scarcely possible to find a limestone that does not contain an appreciable percentage of magnesia; whilst on the other hand the magnesia may occur in such percentage that the stone becomes a magnesian limestone or Dolomite, which normally contains: Lime 30.40%; Magnesia 21.70%; Carbon dioxide 47.90%.

In addition to silica or silicates and magnesia, all limestones contain more or less of what someone has aptly called the "Intruder into everything on earth" viz., iron in the form of iron oxide or iron sulphide.

The principal industries that call for limestone as one of their raw materials are: Calcium carbide, Chemical Wood pulp, Portland cement.

The object of this brief paper is to state in a general way the characters of the limestone required in each of these industries, illustrating by reference to Canadian limestones that have been analysed by the writer.

(A) Calcium carbide.—A limestone to be suitable for the manufacture of this article should be as nearly as possible pure Calcium carbonate. The presence of magnesia is particularly detrimental. A small percentage of siliceous matter and a little iron oxide may be tolerated. These points are illustrated by the following analyses; 1 is being used in a Canadian Carbide works; 2 and 3 are unsuitable for Carbide: 2 because of the magnesia it contains; and 3 on account of the high percentage of siliceous matter.

	I	II	III
Insoluble	...	2.14	10.92
Carbonate of lime	96.89	52.00	87.71
Carbonate of Magnesia	1.64	42.71	.30
Iron Oxide	....	2.20	.70

(B) Chemical Wood Pulp—For soda pulp, i. e. pulp made by "cooking" the spruce or other wood in a solution of Caustic soda, any ordinary good lime-stone will yield a lime suitable for causticising the soda.

But in the case of Sulphite pulp, it is otherwise; selected material is required. In this case the presence of magnesia is desirable, indeed the higher the percentage of magnesia, the more desirable is the stone. But iron is decidedly objectionable; its presence causes discoloration of the pulp.

The following analyses are of Canadian limestones.

I is an excellent stone for sulphite pulp. II whilst good in other respects contains too much iron. III does not contain sufficient magnesia.

	I	II	III
Insoluble	2.10	2.14	.14
Carbonate of lime	56 21	52.00	98.78
Carbonate of magnesia	41.20	42.71	Traces
Iron oxide	.09	2.20	.19

(C) Portland Cement—This article is made by calcining a mixture containing proper proportions of silica, lime and alumina; this is usually a mixture of limestone and clay. A somewhat wide range of material is admissable in this industry. Magnesia is debarred to the extent that the finished cement must contain less than 3% of magnesia.

A limestone comparatively high in silica is admissable here, provided a clay or shale rich in alumina is obtainable.

A certain kind of impure limestone is the sole raw material for certain kinds of Portland cement. This is commonly known as natural cement rock. It is really an argillaceous or shaly or clayey limestone; that is, it is the materials for Portland cement ready mixed by nature.

The following analyses illustrate the statements just made.

I is an ordinary limestone suitable for cement. II contains too much magnesia. III is a natural cement rock.

	I	II	III
Insoluble	1.51	20.23	24.74
Carbonate of lime	97.21	50.37	41.80
Carbonate of magnesia	1.15	24.63	8.60
Iron oxide	.17	2.81	6.30

John W. Edwards and A. T. Hughes, slate manufacturers of Granville, N. Y., have returned from a trip to Newfoundland, and express themselves as much pleased with the slate prospects. A syndicate, in which Granville parties are interested, is now at work there.

AGENTS FOR CANADA

A CORRECTION.

Toronto, Feb. 28th, 1901.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Mr. Bishop, Architect of the Public Schools, Toronto, has brought to my attention the report of my remarks at the recent Convention of the Ontario Association of Architects.

The rough report of my remarks was looked over very hurriedly, and I am sorry I am quoted as having said, "The ventilation of our schools was criminally neglected."

I have no recollection of using the words "criminally neglected," and certainly would not use them, but I think I was referring in my remarks to some 28 class-rooms which I inspected two years ago, used as a temporary accommodation.

Many of the schools are as regards fresh air well supplied if not overcrowded, and I am glad to learn from Mr. Bishop that arrangements are being made for supplying adequate moisture, and in new schools for mechanical means of ventilation.

I shall be obliged if you will give this note space in your next issue.

Yours truly,

P. H. BRYCE.

ENGINEERS VERSUS ARCHITECTS.

A lively game of curling was played at the Granite rink, Toronto, February 26th, when architects and engineers laid aside their T squares and wielded brooms instead. It was a close game throughout, the following being the score:

Engineers.	Architects.
W. R. Clement	A. H. Gregg
C. B. Smith	A. R. Denison
J. D. Shields	F. H. Herbert
C. H. Rust, skip—10	J. A. Pearson, skip—9.

Mr. W. H. Elliott, of the Elliott & Son Company, the well known decorators of Toronto, accompanied by Mrs. Elliott, is on his way to Europe. His intention is to visit the leading art centres in Great Britain and on the continent.

NOTES.

Mr. H. S. Griffith, architect, of Winnipeg, has recently taken into partnership Mr. Thomas Kennedy.

Mr. F. Neil Brodie has recently opened an office for the practice of architecture at 42 Princess St., St. John, N. B.

Mr. Harry Staveley, the well known architect of Quebec, has taken into partnership his son, Edward B. Staveley, who recently completed a course of study in the architectural department of McGill University, Montreal.

Dr. A. P. Coleman, Professor of Geology at Toronto University, and geologist to the Ontario Bureau of Mines, has been appointed Director of the Geological Survey at Ottawa, in succession to the late Dr. G. M. Dawson.

A cable dispatch brings intelligence of the death in action in South Africa of Mr. Frank Douglas of the Oxford Yeomanry, who was formerly a pupil in the office of Mr. D. B. Dick, architect, Toronto, and who has many relatives still residing in that city.

A very pleasant event occurred at St. Thomas a few days ago, when the warden and members of the county council of Elgin waited upon Mr. Darrach, architect of the new county buildings, and presented him with a complimentary address accompanied by a photograph of the new buildings. The committee stated that the result of Mr. Darrach's work had far exceeded their expectations.

Mr. Thomas R. Short, who has been declared the winner of an important competition for model tenement houses for New York, is a native of Hamilton, and was a student in the office of Mr. James Balfour, architect, of that city. Mr. Short has resided in New York since 1885. In the above mentioned competition there were 170 competitors and 308 sets of plans.

According to the Wallpaper News, of New York, a paper that will retain painted or printed characters, and that can be washed, disinfected, or scrubbed, is now made. The paper, either before or after printing, is gelatinized, and then treated with a solution of formaldehyde, which renders it thoroughly waterproof and impervious to moisture. It is especially suitable for wallpaper.

A company has applied to Congress for leave to lay underground pipes in the streets of Washington, the U.S. capital, for the purpose of distributing cool air through residences and business establishments. The air will be pumped through a refrigerating plant.

To canvass a room cover the matchboards with strong calico known as Bolton twill, fastening all round the edges with copper tacks an inch or two apart. Stretch as tightly as possible. When fixed, apply a coat of very strong size. For a good job the calico should be interlined before putting on the wall paper.

THE British Fire Prevention Committee are organizing a novel demonstration in the form of a fire-proofing section in connection with the Biennial Building Trades Exhibition at the Agricultural Hall, London, in April. A large gallery has been retained for exhibits showing progress made in combating fire by improved materials and systems of construction. This exhibition will not not only be the first of its kind in any country, but will show that the reduction of fire risk by improved forms of building has now its own independent industrial position, claiming not only the attention of professional men but the study of our local authorities.

Canadian Industries and Canadian Products are taking the lead the world over. Why should not Canadian Varnish do so at home? When making out the specifications for your next building, remember that

EXAMINATION
TO
Qualify for Associateship
IN THE
Royal Institute of British Architects

The Royal Institute of British Architects, desiring to give facilities for those in the Colonies, to qualify by Examination for Associateship in the R. I. B. A., have decided to hold an Examination from June 21st to 27th, 1901, in Montreal. Applications, Fees, and Probationary work must reach London not later than May 5th, 1901. Intending candidates, who must be over 25 years of age, can obtain application forms and copies of the previous examination on application to

ANDREW T. TAYLOR,
Hon. Secy. R. I. B. A. for Canada,
43 St. Francois Xavier St.,
Montreal.

NOTE.—Those who are members of recognized architectural associations who have passed the regular final examinations appointed by such associations, are exempted from submitting probationary work, but evidence of passing such examination must be given.

FIRE-PROOF GLASS WINDOWS
THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

Decoration of the Grand Dome at the Glasgow Exhibition.

WITHIN the brief space of six months two young Glasgow artists, Mr. John Dall and Mr. David S. Neave, neither of whom had any previous experience in mural painting, have successfully planned and executed a scheme of decoration for the grand dome of Glasgow Exhibition. The space to be covered measures 226 feet in circumference and 65 feet in height. Within this space have been placed thirty-two figures. Each figure has been cut out of its canvass and hoisted into its place, where it is fixed to the wall. On the cup or curved portion of the dome two large-winged angels with palms and laurels face one another, each with an attendant figure at either hand, the composition being connected by six groups of flying amorini. A gilt frieze runs round the circle, and below this are fitted at the window spaces eight seated figures in four groups, symbolic of industry, commerce, science and art. The whole is set in a very decorative landscape background.

The School of Practical Science.

It is gratifying to state that the Ontario government have promptly responded to the request of the students and interested bodies for increased accommodation and better equipment at the School of Practical Science, Toronto. The goverment's determination to erect an entirely new building for the purpose is a wise one. The estimated cost is $200,000, but a larger sum will be expended if the requirements should demand it. The designing of a building for such a purpose will afford scope for architectural ability of a high order. Probably the most satisfactory method of procuring a carefully designed and planned building expressive of its purpose and adapted to the requirements, would be to institute a competition for designs under conditions to be approved by the Ontario Association of Architects. The government should give the winner of the competition opportunity to inspect the most important buildings of similar character in the United States, the desirable features of which should be incorporated in his plans. The determination to spend so large a sum upon the erection of a building, the equipment for which will call for a further considerable expenditure may be taken to mean that the government propose to establish one thoroughly efficient scientific school in Ontario, instead of dividing the money at its disposal between two or more institutions. We strongly sympathize with this idea. Let us have one provincial university and one scientific school which will compare favorably with those of other countries, rather than a number of such institutions which because of insufficient revenue must necessarily be more or less inefficient.

The Licensing of Architects.

THE American Architect correctly points out as one of the objectionable features of the Illinois law compelling all architects to be licensed, that it restricts the practice of architecture to architects resident within the state. The Quebec law on the contrary admits to practice within

the province all architects who are certified to be members in good standing of an architectural institute or society, as well as persons who have passed the qualifying examinations prescribed by the Province of Quebec Association of Architects under authority of the Quebec Architects' Act.

The Building Outlook.

THE indications point to a season of considerable activity in building. A majority of the architects are now busily engaged on plans of new structures and alterations to existing buildings. Quite a number of contracts have already been let in Ontario, but in the eastern provinces the weather is not sufficiently favorable for the commencement of operations. The bulk of the contracts are believed to be as yet unsigned. Many architects and building owners prefer to wait until the market for materials and the scale of wages for the season can be accurately gauged. Conferences of employers and employees in several of the trades have been held, resulting in agreements to advance slightly the scale of wages. It is not believed however that these advances will in any degree hinder the carrying forward of building enterprises. Prices of materials remain steady. The high price of lumber undoubtedly checked building progress last year. Some projects were held over in the belief that lower prices would rule this season. Such is not likely to be the case however. The activity of demand, coupled with the growing scarcity of good lumber has prevented any decline, and prices are likely to rule higher rather than lower in the future. In Toronto the growth of population calls for a large increase in house accommodation, and considerable activity is already manifest in that direction. The erection of the new Toronto hotel, the site for which is now being cleared, will afford an outlet for large quantities of materials, provide employment for a small army of artizans, and be the means of greatly improving the appearance and trade of a locality which for some years past has suffered a decline.

THE PREFERENTIAL TARIFF AND TRANSPORTATION.

The preference of 33⅓ per cent. which is granted by the Canadian tariff to British manufactured goods entering Canada, appears not likely to benefit British manufacturers to any considerable extent. The reason is that United States manufacturers, in their determination to maintain their hold on the Canadian market, are cutting the prices of their goods to Canadian buyers to the extent necessary to enable them to undersell the British manufacturer, notwithstanding the advantage which the latter enjoys under our tariff. In order to do this, United States manufacturers are selling their goods in Canada at prices much below those charged to their customers in the home market. The only person, therefore, who is being benefited by the preferential tariff is the Canadian consumer.

Discrimination in railway freight rates also enables United States manufacturers to undersell Canadian manufacturers in their own market. As an illustration, we may take the case of corrugated iron. Every sheet of this material used by Canadian manufacturers must be brought into this country from the United States. Most of the material comes from Pittsburg. We find that the Pittsburg mills are selling the finished product to the customers of the Canadian manufacturers to whom they supply the sheets. On account of lower freight charges, the Pittsburg mills are able to ship the manufactured material to British Columbia, pay 25 per cent. duty, and undersell the Canadian manufacturer in that market. They can lay the finished product down at $1.00 per 100 lbs. plus the duty, while it costs the Canadian manufacturer $1.48. The Canadian Pacific Railway Company claim that they cannot meet the rates granted by the American roads, although their freight carrying facilities are not fully taxed. Surely it would be better for them to carry Canadian goods at a small profit and thereby help out the Canadian manufacturer, than allow his trade to go to the United States manufacturer and the goods to be entirely carried by American roads.

It will be seen that the tariff question has become one of the greatest importance in Canada. Some means of regulating rates and conditions are needed. Whether the proposal of the government to appoint a railway commission would effect the object in the most satisfactory manner is a difficult question to determine, and one which would largely depend on the powers and privileges granted to the railways by their charters. If such a commission is appointed, it should be entirely beyond political influence, and should be so constituted that the character of its administration would be continuous, giving opportunity for the members to become thoroughly familiar with the questions with which they would be called upon to deal.

The proposition has been brought before the Canadian Manufacturers' Association that the preference should only apply to British goods brought into Canada through Canadian ports. This proposition has in view the laudable object of building up Canadian seaports, but there are other phases of the question which are equally important and which must be taken into consideration. If Canadian manufacturers are to successfully compete with those of the United States for foreign trade, they must enjoy equal shipping facilities. It is evident that we can only bring to Canadian ports as many ships as we can supply with cargoes, and that the frequency of their arrival and departure must also depend upon the volume of shipments. With a population less than one-twelfth that of the United States, and with seaports much less advantageously situated, we cannot hope to be able to give our shippers for export as good facilities as they now enjoy by the use of American ports. Under the bonding privileges which now exist, they are placed on equal footing with the shippers of the United States, while if they were compelled to use Canadian ports, they would be subject to delays which would make it impossible for them to compete.

A DESCRIPTION of the granite sarcophagus in which the Prince Consort's remains were interred at Frogmore is published in the Aberdeen Journal. The sarcophagus, with its lid, weighed nine tons, and was drawn through Windsor with eight horses. It was formed out of a single block of Aberdeen granite, and was constructed to contain two coffins. Three of the eight workmen employed in the construction of the sarcophagus are still living.

"Effective advertising is the kind that is always fresh and interesting. If there are several things to talk about, talk about one at a time, and talk about it so that it will make an impression. Don't say the same old things over and over in the same old way.

THE ART OF DESIGNING SMALL HOUSES AND COTTAGES.*

BY BARRY PARKER AND RAYMOND UNWIN.

IN no house can every advantage be obtained; each must be somewhat of a compromise; in each there must be a sacrificing of what we deem the less important to secure what we esteem of greater value. It follows that the variety of our attitude must produce individuality in the results.

Suppose we have received a commission for a dwelling house. The first thing is to visit the site and devote some time to thinking out the problem on the spot. The site is the most important factor to be considered, for it usually suggests both the internal arrangement and the external treatment. If the site is a large one the position of the house upon it must first be determined.

A primary consideration must be to place the house as to afford its occupants the greatest possible enjoyment of such beauty of adjacent country or grandeur of distant view as the site can command. While doing this, however, we must so place and design the house that it shall not stand out as a disturbing excrescence, but shall look at home in its place, in harmony with its surroundings.

This consideration of the house as a detail in a larger picture will bring us to a detemination of its general form, its treatment and its colouring. Some positions demand a lofty building to crown or complete a spur of rising ground, for example, while others seem to suggest that it be kept as low as possible, as when it nestles under some protecting hill-side. And in the country at any rate the low house is usually more successful. Some natural terrace may suggest a long house with all its rooms facing one way, or a ridge may indicate a double-faced house commanding the outlook over each slope, or perhaps a steep hillside will require a house following its lines and clinging to it storey by storey, while a gentle slope will demand a general grouping of the roofs to give a sense of stabilty by contradicting it.

In the choice of materials and colouring, harmony rather than strong contrast should be sought. There is only one sure way of obtaining this at all generally, which is of course to keep to local materials and local ways of using them. In some places a low-toned colour-scheme, such as stone walls and grey stone or slate roof, seems most fitting, in others the warmth and brightness of bricks and tiles; some invite the homeliness of whitewash, while others suggest the deep colouring of green or purple slate. Whatever it is, some definite colour-scheme should be adopted and colours of paint and any enrichments made to contribute to it.

Greatly as must the site influence the external treatment of the house, its internal arrangement will be even more definitely dictated by it. The position of each room in relation to the points of the compass and the outlook should be determined on the spot. It is now pretty generally realised that no sacrifice is too great which is necessary to enable us to bring plenty of sunshine into all the main living-rooms. The general rule would seem to be, to so contrive as to get the sunshine into a room at the time when it is likely to be most occupied. Let a study or breakfast-room be east or south-east, a general living-room or drawing-room south and south-west. A good western window in the room we most occupy in the latter part of the day gives us many an extra hour of daylight; while the opportunity it affords us of habitually seeing the bright colour of sunset is a privilege which is worth some effort to obtain. A kitchen is best north-east or east, for the first coming down into the fireless house may well have its cheerlessness reduced by what sunshine is to be had at an early hour; later in the day, when the kitchen is hot with cooking, the heat of the sun should not be added. A bathroom and bedrooms too are pleasant with an eastern aspect, though some cannot sleep in a room into which early sunshine can penetrate.

Next only in importance to such considerations of aspect, and certainly important enough to modify them somewhat, is the question of prospect. For a pleasant outlook is a boon second only to a sunny aspect.

Before leaving the site one should be able to carry away not only detailed notes of drainage, water-supply levels, fine trees, views and aspects, but also a general idea as to the arrangement of the rooms of the new house, an ideal plan to be aimed at, and a sort of mental sketch in block of the general form the new creation should take externally.

It would be only tedious to you if I were to go through all the details of a house, trying to deal with them in a general way. I will therefore take one or two definite examples and explain how and why we worked them out as we did, trusting that the interest which attaches to any active problem solved may come to my aid and redeem the details from tediousness.

We have chosen for the first example a country-house designed for a house in North Saffordshire, partly because the site was not one to very obviously suggest or very imperatively demand a special treatment. The plot of land consists of a small field, long and rather narrow; it is much the shape of a suburban building plot, though situated right in the country (see illustration pages.

The client required the house to have a good comfortable living-room for the general family life; another good room for entering guests and callers; a small den for his own use, with desk, safe, sample cupboards and gun-rack; four bedrooms, one to be a bed-sitting room for an only son; a kitchen with the usual offices; outside there were to be wash-house, stables, coach-house, &c. The house was to be arranged to give as much open-air as possible.

As the site is exposed to the prevailing winds, and the best prospect is in the direction whence they blow, some form of court on to which the rooms might open suggests itself as a means of obtaining the needful shelter. The stable yard not being very suitable for the purpose, the house is grouped round a very small central court, round which a corridor is planned fitted with sliding windows, so that it can be converted at will into a sort of small open-air cloister by sliding the sashes down below the sill. This is roofed over at as low a level as possible to avoid anything of the feeling of a well, which a court as small as this needs must be might soon produce. The main roof also is made to slope away from the court in all directions, so that a good deal of sunlight may find its way in. On to this corridor the main rooms open with wide double doors, and the court being protected against wind on all sides it is possible in any weather, except when extremely cold, to have the living-rooms open to the fresh air to a quite unusual extent. The kitchen, butler's pantry, front and side entrances, and stairs all communicate

* A paper read before the Society of Architects February 7th, 1901. For illustrations, see illustration sheets of this number.

with the corridor, but so as not to destroy the privacy of the living rooms by obliging anyone to pass the doors when going from one to the other. Pleasing vistas are obtained from the rooms across the court, and from the corridor into the rooms, such as it is not often possible to contrive in so small a house. Provision is made in one corner for a ventilating stove to prevent excessive cold draughts in winter.

The living-room, as the most generally occupied, and therefore most important room, is placed at the south corner, having the double outlook to south-east and south-west, and getting all available sunlight and the best of the prospect. It is not enough to give a room windows in the right direction, however : the room must be so arranged that it shall, so to speak, turn its right face, and the windows be so placed that they shall be naturally seen out of from the most usually occupied parts out of the room. For this reason an angle window commanding the best part of the view is thrown out on the south-east side. The fire is put on the north-east wall, and, so that a thorough sense of cosiness may always be obtainable, it is placed in a deep recess or ingle.

Now an ingle affords a very good instance of how easy it is to misuse the old examples which we study, and that in two directions. For while some neglect altogether the suggestions which they offer, others copy the old forms without troubling to understand them. To make use of old features legitimately, of course one must first understand the reasons which called them into being : the difficulties which they were designed to meet ; and when similar reasons or difficulties present themselves to us we may then avail ourselves of the solution which they indicate, not copying slavishly the details, but taking the principle and working it out to suit our own particular circumstances. The ingle, of course, had two main uses : the first was to protect a wide open fire from the cross drafts arising from badly fitting or open doors, shutters and windows ; the second was to afford seats near the fire, sheltered from the draughts, where the aged and feeble could rest or any one could keep warm in cold or rough weather. Incidentally, no doubt, our forefathers appreciated the value of contrast, the charm of the ruddy fire-light space glowing red in the ill-lighted building, and the cosiness of the sheltered low recess in the wide and lofty hall. To obtain this charm, as is often done, by forming an ingle so small that one cannot sit in it comfortably, is merely to remove the fire further from the room ; while on the other hand, to arrange a large ingle, as is also sometimes done, with a modern tiled register stove set in a chimney breast is to lose the feeling of "sitting on the hearth" and the charm that springs from the fire being able to cast its glow all over the recess, and to be seen from every part where one can sit. To adapt the ingle rooms of moderate size then and justify the space it occupies, it must be large enough to be comfortably sat in regularly : a place where one can live, not merely go to be roasted. The fire must be so designed as to have something of the feeling of the old fire on the hearth, and must not be cut off from the recess or in any way allowed to grow into a fireplace within a fireplace. It is generally well to make the whole recess into the hearth, and we often arrange for the fire to burn in a suitably-shaped fire-brick hollow, which answers all purposes excellently. Fenders are best avoided, and anything like a loose coal-box is a disadvantage. A coal-box can generally be contrived in the thickness of the wall. The ingle must of course be protected from cross-draughts, otherwise the fire cannot be sufficiently exposed. When properly arranged and fitted with comfortable low seats, the ingle always proves to be a favorite part of the room : the place where people naturally go to sit and rest.

But I am digressing from the plan, and must return to the living-room which we are designing. There the ingle is of somewhat special construction, having several small windows to afford peeps out towards the court and the view, and to give light conveniently placed for anyone reading ; and also having cupboards for the display of the clients's collection of oriental pottery which is being utilised somewhat by way of decoration, where the changing lights falling on its bright colourings will give some additional variety to its beauty. The ingle is made deep enough for the seats to serve for sofas.

As meals will be taken in this living-room, a small dais for the purpose is provided in full view of the fire ; and, by the client's wish, the recess for this is made a window recess in the form of a large sunny bay, having fixed seats on three sides of the table. This bay gives us another window facing directly to the best view as well as one to the west, which brings the evening light into the room, while the recess is a great advantage, as it prevents the room being blocked up with the meal table.

Near the door a slight recess is formed for a sideboard ; and this end of the room is lighted by a window close by, which opens on to the balcony. A recessed balcony is, in our climate, much more useful than any projecting verandah. It is possible, owing to the extra shelter, to sit in such a balcony two or three times as often as in the verandah with open ends.

In this room all the important furniture forms part of the scheme : it is thought out and designed with the building. In the treatment of the room advantage is taken of the beams and lintels required for the recesses, and where these are lacking a deep picture-rail carrying line with them is adopted, under which the side-board, cabinet and windows are arranged to finish, leaving an unbroken frieze above and giving a sense of order and unity to the whole. This frieze is decorated with a painted suggestion of landscape, but in simpler treatment if whitewashed, or tinted with the ceiling, would be light and satisfactory. The lower portion of the walls, under the decorated frieze, is finished in plaster tinted to the required shade by mixing colouring matter with the skimming coat.

Where economy is any consideration rooms may be kept as low as possible, giving additional space subwards, which is as valuable as space upwards, for an air reservoir, and for all other purposes so much more valuable. The house being described is 9 ft. from floor to floor.

The hall or entering-room being intended for less constant as well as more formal use takes a somewhat simpler form. Placed at the west corner with windows south-west it gets all the sunshine during the afternoon and evening, when it is most occupied. It is placed so as to be immediately accessible from the entrance, and opens on to the balcony with folding doors and window. The fire is placed in an ingle contrived under the stairs and half landing, an arch being used in this case to carry the chimney stack and form the recess. The flue from the fire is brought over on to the arch by means of a copper hood. A little bay partly in the porch lights

this ingle. The porch is also arranged under the stair landing, with a seat for a messenger under the stairs.

Adjacent to the entrance is the small sanctum. Here, again, something is taken off the square room, which, while improving it rather than otherwise by giving a recess, for desk and pigeon holes, enables us to have a small vestibule with cupboard for visitors' hats and cloaks.

Handy to the entrance and to this room is the main coat-cupboard and the lavatory, from which a side door leads to the stable yard, while the butler's pantry completes this north-east side of the little court. Beyond this and behind the living-room, having its fireplace at the back of the living-room fireplace, is placed the kitchen. It occupies the east corner of the house and has its main window to the north-east, the right aspect for a kitchen. There is a small window to the south-east, to light the range and make it a comfortable place for sewing or reading. One corner between fire and and window should always be kept free from doors in a kitchen, so that there may be a place to sit in, and it makes a more comfortable kitchen still where it is possible to collect the doors on one side only. Here an arch-way, closed by a heavy curtain when work is done, leads to the scullery, cellar, larder and back door.

The larder has its window in the back porch to get a north aspect, while thorough ventilation is secured by an opening on the south-east up under the eaves where sun cannot reach it. The cellar was added after the preliminary plans were made, the scullery being re-arranged to receive it. This latter is made to obstruct as little as possible the squint window in the living-room ingle, and at the same time gets a south window, which, as there is no fireplace, is a good aspect for it.

The staircase rises from the corridor, and as it is accessible from all parts without passing the doors of the reception rooms, a back staircase is not needed. Where economy is a consideration the back staircase is one of the first things which may be dispensed with, for it adds little real comfort in proportion to its cost.

The bedroom plan follows pretty closely the ground plan, the bedrooms also leading off a corridor round the inner court. The balcony is repeated on the first floor, and, by reason of the parapet and overhanging eaves, it is even more sheltered than that on the ground floor, and makes it possible in two bedrooms to sleep practically in the open air in almost all weathers. It has special value, too, as an addition to the west room, which is designed for the boys' bedroom and study. Here the bed fits in a deep recess out of the way ; a washstand is contrived in the sill of the window of the same recess, which is slightly bayed to give the needful room, and a curtain may be drawn across, cutting off all the special bedroom appliances, so leaving a good comfortable study.

The central court enables the corridor to have opening windows to three aspects, so that some can be opened whatever the direction of the wind ; it also makes it possible to cut on the bathroom, housemaid's closet, and w.c. by means of a lobby having two little windows on to the court.

Of the treatment of the rooms little need be said. The recesses by the chimney breast are fitted with cupboards and book shelves, which are designed to include simple framings or mantels for the fireplaces ; the cornices are arranged to match the cornice over doors and windows and to carry line with a picture-rail running round the room. Wallpapers or other decorations stop at this rail, all above being taken in with the ceiling. This arrangement enables the ceiling to be broken up with the slopes of the low roofs without giving the ugly odds and ends of papered wall, which really are the only unpleasing feature about a ceiling broken up in that way.

During the whole of the planning the elevations are of course kept in view, and the block design carried away in the mind from the site constantly exerts modifying influence. The difficulty usually is to maintain sufficient simplicity ; so many features are suggested by little conveniences of planning that one has more often to cut them out, not too seek for them merely for the sake of effect.

This plan which we have just considered representing, perhaps, rather a large house to be classed as "small," does not quite illustrate one point to which we attach very great importance in the designing of small houses. The two plans on illustration page show this—in which a special effort was made to obtain one room (the hall) giving some sense of space in a house not large enough to contain several large rooms. In every small house it should, we think, be a first consideration to secure one room large enough to afford some opportunity for interest being worked into the room itself, and to allow some comfort and dignity in the life of its occupants.

In the house shown the hall was made into the chief living-room and carried up two storeys to permit the introduction of an organ gallery. The gallery leading to the balcony, the landing, and the staircase are all thrown into this hall, the stairs being so arranged as to afford a screen to the fire, forming a sort of deep ingle with low ceiling under the landing. The low ceiling continues under the organ gallery and the balcony, the central part of the hall being open to the full height. The sense of cosiness in this ingle is greatly enhanced by contrast with the lofty open space outside, while the variety in lighting—whether when the morning sun streams in at the great east window, or when the ingle glows red in the gathering dusk—adds a perpetual charm. In the gallery is a second fire with a lounge seat by the organ under a kind of canopy formed by the half-landing of the second-floor stair.

To obtain this spacious hall the remainder of the house has been reduced as much as possible. Only one other small room, for den or mealroom, is provided, with kitchens, offices and four bedrooms, two of which are on the second floor. It is open to question whether it would not have been a wiser use of the space to have thrown the vestibule also into the hall as was at first intended. Much dignity would have been added to the entrance thereby, while the way from the kitchens to the bedrooms would have been even less through the living parts of the hall than now.

Lest you should be inclined to think that only for people living a very exceptional life would it be advantageous to throw so much space into one room, I will next refer to a design made for a London literary man, who, though not able to afford a large house, still by reason of his position, required occasionally to be able to entertain a good deal of society. Here the first consideration has been to obtain a hall which would be at once a comfortable living-room and a dignified entertaining room (see illustration pages). The meal-room has been kept as small as would just allow a little dinner party to be given in it. The fire is placed in one corner,

the sidehoard in another ; had it been possible to put the door also in a corner it would have been still more convenient, for in a small dining-room it is in the corners that there is a little space to spare.

The narrow Hampstead building plot, having a southern aspect and the best prospect to the south-east dictated the general arrangement of the house and the placing of the best room at the south-east corner. This room is spanned by two arches to carry the wall of the study over ; within one of them is placed the fire recess with seats and fitment, thus using up all the space under the stairs to add to the size and character of the room, while the stairs themselves, which are shut off from the vestibule by a door, are also open to the room, the quarter-landing forming a small gallery overlooking it.

The staircase is such an essentially interesting and decorative feature in a house that it always seems a pity to shut it off in a mere passage, and the space under and around it may be made to add so much to a room

THE PAN-AMERICAN EXPOSITION.—UNITED STATES GOVERNMENT BUILDING.

both in size and individuality. In old houses the charm of such features is well recognised, for the favourite view, alike for the artist and the photographer, is that which contains some peep of stair from the hall, some gallery, balcony, ingle or deep window recess. When the most is made of such advantages as can be claimed for the bare square room, they seem but a poor compensation for the loss of character and charm.

Over the hall in this house are placed the client's studio and bedroom, the two being so combined that both may have the benefit of the whole air-space, bookcases and curtains screening off the bedroom portion. Double doors and double windows are fitted to this room, for perfect quiet both by day and by night is essential, and further to secure this, ventilation is obtained by means of two fire-places with an air shaft built in one of the stacks.

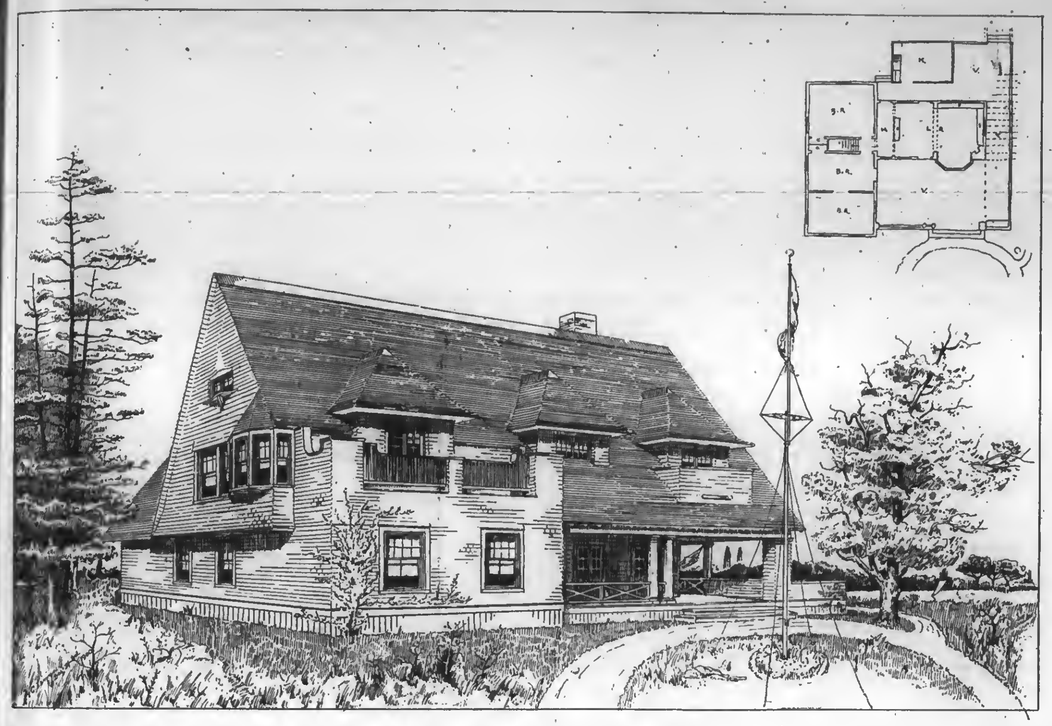
But I must pass on now to cottages, the second part of our subject. I propose to regard as a cottage any house in which separate accommodation is not provided for servants.

To cottages then all that has been said about the advantage of securing a good living-room, even at great sacrifice of other conveniences, applies with additional force. For not only is the total space at our command usually less, but the number of functions which the living room has to provide for is greater, many of the functions of a kitchen being added to it. To combine the comforts of a living-room with the convenience for work of a kitchen will tax our skill in planning, and as the space we can give becomes less our care in the disposal of it must become greater.

Let us again proceed by way of example, taking a rather large cottage designed for a client who wished to live a quiet, simple life, yet on the scale that would allow of his enjoying the more necessary comforts and refinements (see illustration pages). The site is near a small Derbyshire town, and consists of a mound used by the outcrop of some shale grit. The site seemed to demand a simple oblong house with plain open roof kept as low as possible, forming a sort of ridge on the step-sided mound.

The western end of the building naturally becomes the living-room, having plenty of window in the desired direction. There is a window to the north to command the best of the view—not a large one certainly, but one so placed that it is natural to look through it from the outer door, placed there that it may be possible to enjoy the charm which a door opening direct from a room on to a sunny garden always gives. Such a door must, however, be so placed that while the peep out is obtained the comfort of the room is not destroyed. Here we have gathered the two doors and the stair foot together in a narrow part of the room out of the way, leaving all the rest of the space comfortably to occupy. The fire is placed on the north wall, in a deep recess.

To this one good room is added a kitchen for the more dirty work, fitted with a small range, a good cupboard for coats and hats by the entrance, a coal-place and larder. Upstairs are four bed-rooms ; one being rather narrow has a bed-recess taken off the larger room to help it, and as it is over the low ceiling of the ingle it gets the advantage of extra height under the sloping roof, and thus the low ceiling, which adds so much to the feeling of cosiness in an ingle, is made to help the bedroom over. Where some such arrangement as this is not possible, we sometimes utilise the space between the low ceiling and the floor above as a



SUMMER COTTAGE, TORONTO ISLAND.

Designed by Charles Lennox.

storage cupboard, and we often take advantage of it for ventilating purposes, by bringing fresh air into the room, slightly warmed by passing behind the fire, and delivering it over the opening to the recess, where it is distributed with the least possible draught. Where an outlet into a flue is desirable to supplement the exhaust due to the fire, we find this a very good place to arrange it. In a room with close-fitting iron casements, sufficiently well built not to leak excessively through many parts of the room. A window on the south side admits plenty of sun, and in addition on this side there are floors, skirting and door. The most frequent cause of a smoky chimney is the want of sufficient air-supply, and some form of inlet is an absolute necessity. In bedrooms we have successfully arranged this through a hollow fender kerb in some places.

All the bedrooms in this cottage are so arranged as to have a fairly comfortable corner between the fire and a window, where one can sit to read or write. An east aspect is obtained for the bedroom, and a linen cupboard warmed by the cylinder is provided.

Of the elevations I need only say that local random range stone is used for the ground storey, while for the upper portion the need for obtaining four bedrooms over a house so narrow required the use of 9 in. brick walls, which are rough-cast in cement. To avoid the expense of dressed stone, and also to connect the two storeys a little, all the windows have brick jamb and mullions, and the rough-cast is carried down over them. The roof is covered with local stone slate.

Time will not permit me to refer in detail to any smaller cottage plans. But enough has, I hope been said to make it quite clear that, whatever the size of the house, we think it should grow, both as a utilitarian plan and as an artistic creation, out of the real needs of the occupants ; and that the art of designing small houses and cottages consists, not in following any accepted code of conventions, however useful these may be in their place, but in working out such a convenient and comely setting for the special life that shall be lived as shall enable that life to expand itself to the fullest extent, not merely unhampered by the building in which it is clothed, but actually stimulated by a congenial surrounding.

CORROSION OF SOFT STEEL AND WROUGHT IRON.

Mr. F. H. Williams, of Pennsylvania, has recently published the results of some corrosion experiments made with pieces of soft steel containing respectively 0.078, 0.145, and 0.263 per cent. of copper. The steel without copper was found to lose 1.85 per cent. of its weight under the conditions of the experiment, while the pieces containing copper lost only 0.89, 0.75, and 0.74 per cent. in weight. Some experiments with wrought iron showed that the addition of 0.393 per cent. of copper to the iron materially reduced its rate of corrosion. Further information with regard to the effect of the presence of small quantities of copper upon other properties of the iron and steel would be of interest.

Architects, builders and influential citizens in New York City have organized the "Work Together" Club. The object is to promote harmonious relations between employers and employees by bringing about reforms directly affecting the building trades.

The City Building Inspector of Ottawa will conduct an investigation into the cause of the recent collapse of a brick building in course of construction for use as a livery stable. Fortunately only one of the dozen workmen employed on the building when the accident occurred was seriously injured.

BRITISH COLUMBIAN LETTERS.

No. V.

At a recent meeting of the R. I. B. A. the necessity of elevating the standard of public taste in architecture was the theme of a very able paper followed by some brilliant discussions and remarks, the whole leading to no very definite conclusion as to how the education of the Philistines might be improved. The solution of the problem is not hard to find; Philistia could scarcely exist if all architectural work was good, for the public only estimates the comparative merit of work by taking as a standard that which they have been brought up to believe to be good; thus, if the great mass of architecture is bad, or say only indifferent, public taste being formed almost wholly by association is necessarily also but "indifferent bad": therefore, Oh, Architects! by raising your standard of excellence you will surely elevate that of the contemned public.

The applied arts and crafts suffer as greatly from the want of discrimination evinced by the majority of architects as from the neglect and ignorance of the public, and there is no one art so hideously misapplied as that of stained glass. In our report of the First Annual Exhibition of the Arts and Crafts Association of British Columbia reference was made to the excellence of the glass exhibited in this line by Messrs. H. Bloomfield & Sons. In such a report it is quite impossible to deal with each subject at length, neither is it desirable to do so in other than a general manner. Objection has been taken to the writer's definition of stamped and painted glass, but on reconsidering the passage the definition seems to be perfectly correct. It is plainly inferred that a leaded glass window to be in correct taste must be in the nature of a mosaic, the actual construction of which should enter largely into the design, in direct contrast to a painted window of ordinary acceptance, which is thus described by W. Somers Clarke:—"In the painted window we are invited to forget that glass is being used. Shadows are obtained by loading the surface with enamelled colors; the fullest rotundity of modelling is aimed at; the lead and iron so essentially necessary to the safety of the window are concealed with extraordinary skill and ingenuity; the spectator perceives a hole in the wall with a very indifferent picture in it, overdone in the high lights, smoky and unpleasant in its shadows, in no sense decorative. We need concern ourselves no more with painted windows, they are thoroughly false and unworthy of consideration." W. Lewis Day appears to have very similar convictions, but his opinions are expressed in a work of considerable magnitude, whereas W. Somers Clarke was obliged to give expression to his views within the limitations of a paper on stained glass in general read in the space of a few minutes before the Arts and Crafts Exhibition Society. In such cases subtle differences have frequently to be disregarded. There are extreme purists who claim that all stained glass that is not absolutely a mosaic of stained glass and lead is painted glass and condemnable as such, and the high nature of the work produced by members of this school entitles their opinions to respect, even though we cannot admit that their arguments are absolutely sound. It is clear that their work is exercising a very beneficial influence over a large section of designers in Great Britain. This extremely severe school probably owes its existence to the prevalence for so long a period of the "painted windows" trenchantly denounced by W. Somers Clarke and is really a protest against the extravagances so frequently indulged in. A paper transparency stuck on to a window is but slightly more objectionable than many of the kalidescopic horrors one meets with at every turn.

Vancouver possesses in Mr. James Bloomfield an artist in stained glass in the best sense of the term. Thoroughly acquainted with the history aud grammar of his art, imbued with a deep love and reverence for the work of the great early European masters, he has none the less avoided the great danger attendant upon a long and ardent study of ancient methods, for the fascination of this study not unfrequently leads to the conviction that nothing which is not old can be good, thus converting the student into a more or less scholarly reproducer of antiquities. No one believes more completely than does Mr. Bloomfield in modern advantages and opportunities, neither can anyone hold more decidedly than does he that modern work will some day surely equal the old and will also possess noble characteristics distinctive of its own period.

Fourteen years ago while acting as a junior draughtsman in an architect's office in England he turned his attention to wood engraving and discovered his own capacity for decorative design. His removal to this country interrupted the sequence of his studies, but opportunity came to him in the guise of an illuminated address presented by the citizens of New Westminster to the Governor General, the Earl of Aberdeen. His Excellency proved his appreciation of the artistic merits of the address by requesting Mr. Bloomfield to prepare designs for a series of medals for the Boys' Brigade of Canada. His Excellency then made it possible for Mr. Bloomfield to proceed to Chicago where he became junior designer to a firm ranking second only in America to Tiffanys. Here our student attended the Chicago Art Institute, drawing principally from the life, but losing no opportunity of gleaning any knowledge of any and everything connected with decorative design; thence to New Orleans as chief draughtsman to a firm of glass workers, but making time to study at the art schools. Finding his progress here unsatisfactory he proceeded to Europe and pursued his investigations into decorative art all over Flanders; so on to London where he worked at decorative painting principally, but seizing every opportunity of studying at the Polytechnic and South Kensington, drawing, too, continually from the life. During this period of unremitting labor he succeeded in seeing a very great proportion of the famous stained glass in the south of England. Sending some sketches of glass to Manchester, Mr. Bloomfield was immediately offered a position there which he had to decline owing to the necessity of completing certain work he had in hand; however this overture was renewed later and accepted and, if possible, he got down to harder work than ever. He was principally engaged upon church windows, hut worked also upon head and tail pieces for type founders, on decorative painting and heraldry. Finally having prepared designs for the memorial windows to the late Bishop Sillitoe he came out to execute the work and has remained ever since in Vancouver. The coast does not yet afford a designer of such resources many opportunities for the full exercise of his powers, but even in slight and quite inexpensive commissions one finds a character and individuality stamped upon the work that is refreshing. The illustrations, on separate sheet, are from photographs in which the play of light and the color values are of course more or less lost, but the broad vigorous treatment is preserved.

During the past season building operations have been fairly steady, both in Victoria and Vancouver. We believe it has proved a record year for the former. In Vancouver several blocks have been completed, principally on Hastings street, in which few vacant spots are to be found between Granville and Cambie streets. Granville street has also made a solid advance between the Depot and the Hotel. The town is now growing so large, and the site covers such an enormous extent of country, some of it "quite in the country" as a matter of fact, that it is not easy to keep track of all the building. It is principally in the West End that residential work has proceeded during the past season, the southern slope towards English Bay showing to a marked extent the tendency of the people to go farther and farther from the business centre. Probably the most important building of the year is the new Roman Catholic Church, "Our Lady of the Rosary," which possesses a fine peal of eight bells. The vaulting is lath and plaster, the shafts of the columns are scagliola and the geometrical tracery is wooden throughout. In spite of this and the fact that much of the detail is galvanized iron, this church is a great advance upon anything else yet built in the city;—we mean, of course, in ecclesiastical work. It is delightful to once more hear the distant bells, even though the ringing is not yet very scientific. In residential work nothing very notable has been accomplished, the larger work being rather pretentious than interesting. Most of the houses are a very local version of Colonial, which was at best but a wooden imitation of the weakest style that prevailed in English architecture, a period in which it is generally acknowledged that art in general reached the extreme low water mark of English history.

The Arts and Crafts Association of British Columbia held its first annual general meeting on the 4th March; the attendance was somewhat meagre, but the report of the work carried out during the past twelve months was distinctly creditable. His Honor the Lt.-Governor was elected Second Patron and Mr. Harry Abbott, Third Patron; W. J. Ferris, President; Mr. R. B. Ellis and Mr. R. M. Fripp, F.R.I.B.A., vice-presidents; Mr. Q. M. Eveliegh, secretary, with a very good committee, in which pictorial art is perhaps a little too strongly represented. It is to be regretted that the craft as a whole do not appear to recognize the value of the work attempted by the Association.

There are rumors of a Carnegie Free Library, of possible art school and even technical schools; Mr. David Blair, of the newly formed normal school, is inculcating elements of art training into the public school teachers. It really does look as though 1901 is to be the year of inauguration of art education in British Columbia. May it prove to be so.

LANDSCAPE ARCHITECTURE.

By Frederick G. Todd.

It would be mere pretense on my part to attempt to cover the subject of Landscape Architecture in such an article as would be available for your magazine, and I have therefore been obliged to omit almost entirely the interesting history of the profession and much else that I might include, and have confined myself to a general discussion of such problems as are constantly arising.

There are two principal styles of Landscape Architecture, the formal and natural styles. The formal style is much the oldest and perhaps reached its greatest perfection among the Romans, where their stately and costly architecture was echoed and re-echoed by their costly and formal gardens. The early ornamental gardening of England was also of the same courtly and formal style, until through the influence of Repton, Whately, Kent and others a reaction was brought about in favor of the natural style, the enthusiasm for which was so strong that many of the old time formal gardens were swept away. We even find Mr. Kent planting dead trees that the ground might assume a more natural appearance. These men were all true artists, however, and laid the foundation for the rural architecture and gardening, which has been brought to such perfection in England. They gradually came to realize that each style had its own mission to fulfil, that the old Roman style with its terraces and straight walks, its fountains and its statues made a pleasing adjunct to the house, even though the rest of the grounds were treated naturally, with undulating lawns and graceful outline of forest and shrubbery.

Japan Ivy on Piers, Destroying Form and Proportion.

In Canada and the United States it is only within the past twenty-five years that much attention has been given to landscape architecture, and the greater part of the best work has been done by that peer among landscape architects, Frederick Law Olmstead, and his associates. The natural style has been popular almost to the entire exclusion of the formal style, and it is to be regretted that this is so, for there are times and places where it is appropriate and where the effects brought about by the use of clearly defined walks and terraces arranged in formal designs and combined with the use of statuary, sun-dials, garden vases, fountains and kindred embellishments, are such as can be obtained in no other way. Although through the influence of Mr. Olmstead and others much good work has been and is being done, it is still the rule rather than the exception to see costly private residences and public buildings standing bleak and lonely without a tree or a shrub to relieve the hard outline of the architecture; or it may be that some planting has been done, but often such disposition is made of the shrubs and trees as to injure rather than help the appearance of the house, and a place of considerable size made to appear small, mean and uninteresting by the dotting of shrubs, trees, and flower-beds over the lawn.

I wish it were possible to dispel the all too prevalent impression that the beauties of landscape architecture can only be applied to extended acres. Lawns and trees being the two essential elements, some of its beauties may indeed be shown wherever we have a rod of grass, a tree and a few shrubs. In the case of a large expanse of ground fortunately situated, the transformations of landscape architecture may be displayed to their fullest extent—the different views, the variety of scene, the effect of light and shade—all are best obtained with ample grounds, but it is none the less true hat the person who has a small city lot with a scrap of lawn and a chance to plant a tree or two and half a dozen shrubs, may study their arrangement with equal advantage.

In the treatment of a country place the first thing to decide upon is the location of the house. There are no hard and fast rules which can be laid down. Everything must be governed by circumstance and by adaptability to surroundings. Convenience and practicability should generally be considered as of first importance, while the different views to be obtained are of almost equal consideration, and sometimes may even take precedence. It is often pleasing and very effective to place the house so that a beautiful vista may be had through the hall or from some large and important window. I know a view of this kind which would be perfect if seen in this way. The foreground is composed of the lawn, while across a pastoral valley studded with groups of large trees there appears the white spire of a church, rising above the tops of trees which shelter and almost hide the houses clustered about. If this view could have been placed on the axis of a large window in the living room, where it could be seen through all the varying moods of the weather, it would have given a beautiful landscape picture changing with every change of the atmosphere, with every rising and setting of the sun and with every season of the year. The morning rooms of the house, especially the breakfast room, should, if possible, receive the morning sun, and as pleasing views as can be obtained. If the grounds are flat and not very large, more can often be made of a place by locating the house well to one side, for a good sized lawn on even one side of the house is usually much more pleasing than a smaller one on each side of the house. The living front of a house should in every case be kept as far as possible from distracting influences. The drive should never be brought to this front of the house if there is any possible way of avoiding it, and the main walks should preferably be kept to one side.

The locating of the entrance drive is an important feature and the land must be studied with care so that every natural feature can be taken advantage of. A gracefully curving drive is usually most appropriate for a country place, but the curves should not be made without sufficient cause. The meaningless serpentine drives and walks which are sometimes seen wriggling up to a house invariably fill one with disgust. Approaching the house it is very important that the first

view obtained shall be pleasing, for one's first view of a house is often the most lasting. I prefer also, if it can be done without a forced appearance, to confine the approach view to the house and its immediate surroundings. For the house is the natural objective point, and to display a magnificent view just before the house is reached divides the attention and neither receives its full share of appreciation. The view then would better be saved to be enjoyed from the other side of the house.

Bridge and Planting well Combined.

The planting about a house depends almost entirely upon the style of the house, the shape of the land and the general character of the existing vegetation; but generally speaking, there should be a small amount of planting about the house, for trees, shrubs and climbers well arranged serve to augment the beauty of the architecture, and often make a less expensive house look finer than a costlier one, which presents nothing in the heat of summer nor the storm of winter for the eye to rest upon but bare walls and harsh outlines unbroken by vegetation. It is often the case that a few shrubs and climbers judiciously placed will bring into closest harmony a house and grounds which without them would have been at never ending war with one another. Caution should, however, be displayed in the use of such plants as Japanese Ivy, for by covering entirely the angles and ornaments of the house they often defeat the very object for which they were planted by destroying every architectural feature and rendering the whole flat and uninteresting. The remaining planting should in general be confined to the borders of the lawn and if that is already surrounded by trees, the planting should be intermittent, in some places allowing the breadth of the lawn to sweep out of sight underneath the trees, and at others to be stopped by a mass of shrubs, for a large lawn whose every part can be seen from any one point of view is much less interesting than one which may perhaps be smaller, but which is more intricate, which has corners and bays into which it is impossible to see, and which allows the imagination to conceive of all manner of interesting things, just as a painting is often more interesting which leaves much to the imagination. The disposition of trees upon the lawn requires much careful study both as to the kinds to be used and the places they should occupy, for some of the most pleasing results are obtained from the light ands hadow cast upon the lawn by the trees. Especially is this true when in the late afternoon the pointed shadows creep out on the lawn and the yellow sunlight drifts in under the branches of the trees.

It is impossible for me in this short space to say much about flowers, but whatever is done, keep the lawn proper in simple turf; don't cut it up with flower beds; put the flowers in masses in the borders of the shrubbery across the lawn where they will have a good background and arrange them in such a way as to have at all seasons masses of color about the border of the lawn, rather than flowers scattered all about which in themself are insignificant. Plant a few tall-growing flowers, such as the Oriental Poppy and the Golden Glow under the breakfast-window, where they will nod a good morning through the window. As regards shrubs and trees whose deformed branches and unnaturally colored leaves are to some a mark of beauty, I should prefer to omit them altogether, but if they must be used by all means put them in a museum by themselves, where they will not strike a discordant note in

An Artificial Pond, Natural Style.

the landscape, but will really prove interesting as curiosities.

In planning for a country place, whether it be large or small, let every advantage be taken of the natural surroundings. Let the style of the house and its surroundings conform to it as much as is practical. Take advantage of a steep bluff, a large tree, or a magnificent view in locating the house, and keep the lawn on the living front of the house quiet and reposeful, unless it may happen that the style of the house and its location demand a picturesque treatment.

The arrangement of the ground about a house built on an averaged sized city lot is an entirely different problem than is encountered in the country estate. There is usually little choice as to the location of the house and it is generally best for the sake of the appearance of the street to have the house front on line with the rest of the houses. This is not always the case, however, for there are times when a slight change in the location may enable us to have a small garden or some other attractive feature. I think that it is even advisable at times to put the house directly on the street and leave all the space at the rear with the best rooms looking out upon it, but such a location would not be made without fully considering the surroundings both present and prospective. It is a great mistake to think of the ground back of the house as wasted or as merely a storage place for ash barrels, etc. These and other similar necessities can be kept in a neat corner by themselves, hidden from view by masses of shrubbery. The remainder of the ground can often be made charming by laying it out formally as a garden or by keeping it as a simple shrub bordered lawn. Shut off from the street by the house it is sometimes possible to obtain in a thickly settled district a private garden or green almost as secluded from the gaze of passers by as if it were in the country. Where planting is done at all there seems to be a tendency at present to over-plant small places. A sort of ruffle of shrubbery is planted around the base of the house, entirely concealing the foundation and giving it a very weak appearance. Contrast with this a house with just enough shrubs and creepers planted about its base to give it a comfortable look of being united to the lawn, and yet with plenty of foundation left to view to show its solidity and strength of character. The best effect is usually obtained by planting the shrubs about the angles of the house and about the front entrance. Climbers almost always add greatly to the appearance and cosiness of a house, and should be freely used about the verandahs. In the various styles of architecture which make use of strong horizontal lines, it is often very effective to train a dark leaved creeper along those lines to further accentuate them, but not to conceal them. A hedge along the street line, or better yet if there is room, an irregular border of shrubs, often increases the privacy of a place and is much pleasanter to look upon than the customary street fence.

In acquiring land for public parks such should be chosen as will best meet the requirements of the city and which will do the most good to the greatest number of people. Usually land which is partially wooded and which has access to water would be the first choice. Both in acquiring the land and in its treatment afterwards it must be constantly borne in mind by those in charge that they are the trustees of lands and funds whose dispositions will have the greatest influence on the future health and morals of the city. If, as is usually the case with parks, it is the intention to do only a certain amount of work each year, nothing should be done until a working plan has been prepared for the whole park. Then the work can be proceeded with as fast or slow as desirable, but above all things avoid spending money for park improvements, which are conducted in a "piece meal" "hand to mouth" way. The result is sure to be costly; it will probably be inharmonious and will lack that breadth of conception which should come from a plan which is the result of mature consideration. The woods should always be preserved as nearly as possible in their natural condition and as a general rule I would avoid using foreign plants to any large extent. It is hardly necessary to add that flower beds would be entirely out of place in any part of a natural park except possibly in the vicinity of a building. If part of the land is covered with a dense wood it should be kept so, and it is a great mistake to try to change the character of a wood by planting small pines under the oaks or vice versa. It oftens happens that there are pine woods and oak woods in the same park and if so, all the better, but this is no excuse for spotting pines all through the oaks. In the same way if part of the park is pastoral with broad meadows of spreading trees, keep it so, or if part is what we might term, like the English park, with noble oak trees scattered about, nothing could be grander. There are cases where it is advisable to change such existing conditions but they are very rare.

In building roads through a park they should be as few and inconspicuous as possible and in all operations, whether it be the building of bridges, shelters, walks or anything whatsoever, let the park scenery be kept as natural and as restful as possible, remembering that such scenery gives us the greatest relief from the noisy confusion and worry of the city and that on this relief, not only our comfort depends, but also our ability to maintain a temperate, good-natured and healthy state of mind.

Montreal, April 3rd, 1901.

A NEW IDEA IN HEATING.

A new method of heating was recently shown in operation at the offices of the Patent Heating, Skirting, and Ventilating Company, Gordon street, Glasgow. The method is to introduce into a room, instead of the ordinary wood skirting, a skirting made of metal. Externally this skirting is like the ordinary wood skirting, of a design to conform with the appearance of the rest of the room, but internally it is divided into spaces through which a heating medium—steam or hot water—circulates. The heat emanating from it is distributed over the room, by means of both radiation and conduction, and the conduction to the floor and walls starts at the place where it is most required—namely, at the junction of the walls and floor. It is claimed for the method that it does not encroach on the floor space, can be applied to any design of skirting, can easily be fitted into existing buildings, and is cheaper, cleaner, more sanitary, and more reliable in action than any other methods of heating.

The Board of Directors of the Toronto Industrial Exhibition Association have appointed the following architects to prepare plans and specifications for the buildings proposed to be erected this year, namely: Manufacturers' building, Gouinlock & Baker; art gallery, Beaumont Jarvis; dairy building, Gregg & Gregg.

As a general proposition, advertising pays. There are qualifying considerations. It must be good.—Advisor.

MODERN CITY MAKING.*

By Albert E. Kelsey.

Modern city-making, speaking in a general way, involves, first, circulation; second, hygiene; and third, beauty. I shall discuss the first two briefly, and, while considering the third, will revert now and again back to the first two, to show the inevitable interdependence of all three.

Circulation represents the anatomy of a city, the transit facilities above, below, and on the surface of the ground, the life arteries, or pipe galleries for the distribution of the public utilities and a sewage system.

Here we see the interdependence of circulation and hygiene.

Hygiene represents the aspect and prospect of the city, its general salubrity, the density of population, the lighting by night and day, a good circulation of air, and, lastly, a proper density of construction.

A fixed ratio should exist between the voids and solids of all quarters of the city, whether it be the lofty office building quarter, or the two or three storey modest residence quarter. By this I mean a proper ratio between blocks of buildings on the one hand, and the streets, courts and open spaces surrounding them on the other. If a sufficiency of open space is provided, beauty is possible, and, here, already, we see the interdependence existing between circulation, hygiene and beauty.

Beauty in modern city-making represents the expression of a city. Cities, like individuals have natural and artificial expressions. The dominating chimneys of the manufacturing town, like the surmounting domes and minarets of the Oriental city, each represent their natural expressions.

In the savage age, men had the same organs they now possess, but they were undeveloped. The savage man was unkempt, shaggy and often dirty.

The natural city is unkempt, that is to say it is a haphazard accretion, and it is usually dirty. But, as these cities develop, whether it be the crude manufacturing town, or the mysterious Oriental city, in this age, they soon produce one or more rosmopolitan thoroughfares, providing easy circulation, good hygienic properties, and possibly, some degree of beauty.

The savage city begins to wash itself. It may be but Pera street of Stamboul— but a "lick and a promise,"—yet it illustrates the fact that all cities have certain requirements in common when they begin to groom themselves, and enter into the competition of the world.

This social adjustment may take away much of the picturesque charm and some of the individuallity of a city, but it returns convenience and a state of well being which more than compensates.

The difficulty now confronting the cities on this side of the Atlantic is not so bad as those that existed in the feudal towns of Europe, and still exists in the semi-barbarous centres of the Orient.

We live under a form of goverament, however, which is not as hospitable to swceping reforms as their's are, and, as it is our ostensible policy to expend public funds for the benefit of the greatest numbers, we should then work for raising the general standard of the entire city rather than the mere improvement and embellishment of spots.

And yet a beginning must be made and, of course, in some spot.

That very acute art critic, Charles Elliot Norton, of Harvard, long since pointed out the necessity of building up a general art appreciation among a people if far-reaching results were to be logically produced, and he suggested object lessons as more potent educational factors than any amount of preaching.

The thought that this work could be entrusted to the coming generation, and that the young at school and at college should be prepared for it by being surrounded by beautiful buildings which should appeal to them unconsciously, and infuse in them a constant desire for the beautiful.

Let me carry this idea further.

If we are to metamorphose our cities bodily, why not seize upon this idea as a popular scheme, and apply it to all the new public school buildings, one by one as they are erected, a scheme that would meet as few conflicting rivalries as any, and one in which nearly every parent would take an interest—an eminently democratic scheme, a scheme which, once set in motion would gradually improve every quarter in turn, thus creating new centres throughout a city's area, around which property would always be improving. And, lastly, it would gradually raise the standard of the entire city, without involving any great expenditure in any one spot. Furthermore, it would set in motion a system of continuous rotation that might be applied to many other public and semi-public institutions in any community, and, as an object lesson, it would always be teaching the lesson of continuity and interdependence, the first principle of modern city-making.

Let us try to envisage our own marvellous times with accuracy as well as with beauty.

To do it we must be alert to feel that pulse of the people, and if we feel keenly, perhaps some may understand clearly enough to record our history with trustworthy thoroughness.

It is certain we can better make our structures represent these, the only times we have known—this, the only era we have lived in—than any past history, no matter how glorious. Beware of Archaeology!

Spontaneity in architecture must spring from a natural every-day impulse. Living architecture must appeal to the beholder and lead the mind forward. It must be progressively anecdotal to stimulate the imagination and to rivet attention.

Let us then try to see things as they are; let us appreciate the scope and universality of modern life; let us grasp the spirit of the times and then build unaffectedly.

To give direction to public sentiment your society can do much. It may agitate through the daily press such improvements as may be popularly deemed necessary, and by taking such an active part you will soon be surprised to find that as matters are shaping themselves artistically your advice will be more and more respected and followed.

However remote or however small these beginnings may be, remember whatever you plan to lay out, construct or re-construct, that it is an integral part of the entire city, not a scattered unit, but one of a system of units.

See to it that only the best talent is employed, and that the design itself is made indigenous in spirit and modern in construction, always remembering that the great on-sweep of the world is weaving itself into the fabric of all great cities, teaching us—not independence—but the interdependence of man.

* From a lecture delivered under the auspices of the Toronto Architectural Eighteen Club at the galleries of the Ontario Society of Artists, Toronto, Feb. 5th, 1901.

HISTORY OF THE ONTARIO ASSOCIATION OF ARCHITECTS.*

In the summer of 1887 some of the architects of Toronto agreed to meet together once a month to dine and talk over matters of professional interest. At the fourth dinner this Club, which by then consisted of twenty-four members, assumed a Constitution and a name, calling itself the Architectural Guild of Toronto.

The Guild soon became so active that when in the following summer the Minister of Education for Ontario, the Hon. G. W. Ross, wished to establish a Chair of Architecture at the School of Practical Science in Toronto, he invited the advice and co-operation of the Guild. A Committee of the Guild met the Minister at his office on October 29th. In the conversation which then took place was suggested the advisability of the architects of the Province of Ontario becoming incorporated as a Society or Association with power to examine and license persons wishing to practice Architecture in the Province.

At the monthly dinner of the Guild held on November 8th, 1888, the idea was put into action by the appointment of a Committee to draw up a scheme for the formation of an Association which would be the first step to the attainment of such incorporation.

The Committee consisting of the following members of the Guild,—Messrs. E. Burke, S. G. Curry, Frank Darling, D. B. Dick, A. R. Dension, H. B. Gordon, Henry Langley, W. A. Langton, E. J. Lennox, Wm. G. Storm, Walter R. Strickland, and S. H. Townsend, reported finally on the 14th March, 1889.

On the 21st March, 1889, in response to an invitation from the Guild, sixty-two architects practising in the Province of Ontario met at the Queen's Hotel, Toronto, and agreed to the formation of an Association according to the plan proposed, passing at the same meeting a Constitution and By-laws and electing officers as recorded in the minutes of that meeting.

At the instance of this Association a bill was brought before the Ontario Legislature, in the session of 1890, by which bill it was proposed that the use of the title "Architect" should be restricted to members of the Association and that, after a certain date sufficiently distant to allow a reasonable time for all architects then practicing to enroll themselves as members, admission to the Association should be governed by examination. The intention was to allow all persons who were making use of the title Architect at the time the Act became law to continue their practice undisturbed, but to require all future aspirants to the title to so qualify themselves, under the necessity of passing examinations in order to acquire this distinction, that the standard of professional attainment in the Province would in the course of not many years be raised; and a finer quality of work, higher aims and a better style of practice prevail as the the natural accompaniment of higher professional training.

It was a good scheme for a new country. In an older country the ancient buildings form standards of comparison beside which faults in modern design can be seen to be faults, so that every old building is a silent tutor of the public taste. But we have no such buildings. The public are led by the profession and the state of affairs gives rise to but little pressure to impel young architects to acquire such training in design as is necessary for the advancement of architecture in this country.

To legislators the measure appealed only as a provision for the safety of the public and they thought this would be sufficiently provided for by giving a distinguishing title, different from the usual title, to architects who had passed the qualifying examinations of the Association; thus setting members of the Association apart as a special class of qualified architects. The bill was accordingly amended in committee so as to make the distinguishing title of members of the Association not "Architect," as desired, but "Registered Architect," and in this form it was assented to on April 7th, 1890. The effect of this change was to kill the movement as conceived—as a universal movement towards the advancement of architecture—and to leave the Association with a struggle before it to attain even the partial effectiveness of a voluntary and partial Association. It proved to be impossible to elevate an arbitrary title over the accepted title; or in other words to degrade the title Architect by law without there being any other reason for its degradation.

If the charter members of the Association had been forced to pass a stiff examination, so that the legal title had from the start a real significance, the result might have been different; but as all practicing architects were of necessity admitted to the Association in order that no vested interests might be injured, the select character proposed for the Association had no real existence, nor could it have any real existence until the ten or fifteen years should pass which were necessary to bring about the retirement of the older charter members and an influx into the Association of young men who had won their membership by fitting themselves to pass the entrance examination of the Association. But this period was a longer time than the Association could be held together to no immediate purpose. The Act was for all practical purposes, in its first years, merely a law licensing practising architects to call themselves Registered Architects. As such it had no influence with the public, and thus the only inducement that the general body of the profession had to support the title and the Association was gone; indeed the most ardent workers for the advancement of Architecture had an objection to the title and did not use it, though they continued to support the Association in its aims and in the work which it still tried to carry on in the way of regulating competitions, testing material, procuring good building and fire by-laws and other public and professional matters, as well as meetings of members for mutual improvement, and annual examinations for students.

After the first year students came forward in very small numbers for examination; so that there seemed to be no hope of establishing even the select body of qualified men that the Act, as passed, was fitted to provide for. But, even if it could be established, a small select body would be of little use as a provision for the public safety. A select body is unnecessary for the sort of public safety which was aimed at by legislators—that is to say to secure the appointment of a competent architect for the construction of great works. Great works are never put into the hands of any but architects of known experience, and the public will select an architect for such works from the elite of the profession, whether they are marked off by an Association or not. On the other hand, for the sort of public safety that can be provided for by act of Parliament, a select body is insufficient, for it is in the diffusion of architectural training that Parliament can best help public safety, by making ordinary building throughout the Province both safe and sanitary; and it can thus help also another matter of practical im-

* Reprinted from Vol. I. of the Proceedings of the Association.

portance to the public, (which is not sufficiently regarded in considering this question,) the return of proper value for money invested in building.

For this reason the Association still hoped to get the more comprehensive measure from the Legislature and made three efforts to obtain it; nor was the opposition they met with such as to give them reason to suppose that there is any real objection to it or that, if it could have been brought to a third reading it would not have received the support of a majority of both sides of the House.

A bill to amend the Act, by making "Architect" instead of "Registered Architect" the exclusive title of members of the Association, was first introduced in 1893, but too late in the session, and was therefore withdrawn.

In 1896 it was again introduced and referred to a committee by whom it was reported to the House, but only on condition that it be then withdrawn. This attempt served as an introduction so that, in the following year, the Bill received support both outside and inside the Legislature; indeed its supporters in the Legislature, who were drawn from both sides of the House, agreed in assuring the Association that there was a palpable majority in favor of acceptance. But the same committee was appointed to deal with the Bill, and this time they dismissed it finally.

The arguments by which the Bill was opposed were in all cases the argument of interests which feared injury. There seemed to members of the Association, who represented the Association in the matter, no cause for the anxiety thus manifested by opponents, but they felt that their arguments in reply failed to carry conviction because they were regarded as ex parte. It seemed impossible for any one to grasp the idea that architects in urging a Bill to improve architecture could be thinking of anything but their own immediate advantage.

The objection raised by Mr. Norman Shaw and others in England—that no amount of examination can produce in a student a faculty of design—was not raised here; but it is impossible to conclude the subject without noticing this protest, raised in the remarkable volume edited by Mr. Norman Shaw, "Architecture a Profession or an Art;" remarkable as being so ably written and yet founded on so palpable a fallacy. It is not contended that examination, or to speak more exactly the education which is called forth by the necessity of examination, can implant in any one the faculty of design; but where there is nevertheless the purpose to design, what little faculty there is may be much developed by study under guidance, and scholarship may serve at least to prevent aberration of taste. It is precisely for this order of designers, and for those who would not otherwise know that there is such a thing as scholarship in design, that a compulsory Education Act would have been useful in this Province.

It is in levelling up all parts of the profession that it would do its chief work; saving us at least from ignorance that does not know that there is knowledge, and helping toward the ideal condition that not only great works but the ordinary types of building should be carried out in a sensible and agreeable manner. As for budding genius—it wants training like any other order of mind to enable it to work to the best advantage; and if there is a doctrinaire position in the whole controversy it is that of those persons who think that knowledge is the death of intuition.

With the failure of its last effort for comprehensive registration the Association became a voluntary Association in purpose, as before it had been in fact, and is now trying to uphold the standard of education in students and of practice in its members by classes and examinations for students and by monthly meetings of members for reading and discussing papers. By an arrangement with the School of Practical Science, students of the Association are able to attend classes of the School for instruction in theoretical subjects; and a studio for instruction in design under the supervision of a committee of the Association is held in the Rooms of the Association at 94 King Street West, Toronto.

These rooms, the latest departure, will without doubt contribute greatly to the usefulness of the Association, giving it such facilities and comfort in work as make work more easily carried on in a continuous way.

The proceedings of the Association will henceforth be printed in a form suitable for preservation and reference; instead of, as hitherto, only as a report in the CANADIAN ARCHITECT AND BUILDER. It has been thought fit, by the Editing Committee to preface the first volume by an account of the origin of the Association and the purpose it at first set before itself of obtaining universal registration of Architects in the Province as the best means of furthering the advancement of architecture which it is now endeavoring to promote by the methods of the voluntary Association.

W. A. LANGTON.

ONTARIO ASSOCIATION OF ARCHITECTS.

The first volume of proceedings of the Ontario Association of Architects printed in pamphlet form has just been published. It comprises seventy-five pages. In addition to the proceedings of the annual convention, it contains a list of the presidents and other officers and committees of the Association; the names and addresses of the members in good standing, a list of the books in the Association library, a brief history of the Association by Mr. W. A. Langton, and views of the Association rooms. The proceedings were published for the association by the publishers of the CANADIAN ARCHITECT AND BUILDER, under the direction of the Editing Committee: Messrs. M. B. Aylsworth, (chairman), E. S. Baker, F.R.I.B.A., W. A. Langton, C. H. C. Wright, R. J. Edwards.

The Association suggested to the City Council of Toronto recently that a plan of the best possible arrangement of wharves, squares, promenades, glass plots, and trees on the water front be prepared, and that the class and location of buildings to be erected thereon be regulated by by-law. By these means the work of improving the city water front would be greatly simplified, and whatever works may be undertaken, year by year, would form part of a well-considered general scheme.

Mr. Frank Darting, architect, of Toronto, has been commissioned to prepare the design for the soldier's monument to be erected in Victoria Square, Portland street, to the members of Imperial regiments who died while on service in Canada.

Negotiations are in progress for the transfer to the Dominion Government of the Plains of Abraham at Quebec, for the sum of $80,000. It is to be hoped that the result of these negotiations will be the preservation for all time of this historic battle ground.

The unveiling of a monument to Laura Secord will take place on June 22nd, and will be the occasion of a military display. The monument takes the form of a life size bust of Laura Secord, modelled by Miss Mildred Peel and cast in bronze. It will be mounted on a granite pedestal bearing a suitable inscription.

PROPOSED NEW BUILDING REGULATIONS.

The Fire and Light Committee of the Toronto City Council have approved of the following recommendations of the Federated Council of Building Trades: That when buildings under construction reach one storey in height the joists shall be covered or floored temporarily with one-inch boards, as each storey is built. In case of steel structures, where girders are 12 feet centres, two-inch plank shall be used with sufficient support in the centre. Where joists are over 16 inches and up to 48-inch centres ½-inch plank shall be used, and where six-foot centres, 2-inch plank. In builders' scaffolds the distance between standards shall be eight feet instead of eight or ten, as formerly allowable. Where trestles are used the height is to be five feet and the material substantial. When scaffolding is formed by putting trestles one upon another, not more than two trestles shall be used, each five feet high. Above the height of ten feet standard-ledger or ropes shall be used. A guard-rail shall be built around the scaffold to prevent bricks falling, and another guard three feet above the scaffold to keep men from falling off.

Canadian Industries and Canadian Products are taking the lead the world over. Why should not Canadian Varnish do so at home? When making out the specifications for your next building, remember that

STUDENTS' DEPARTMENT.

METHODS OF THE ECOLE DES BEAUX ARTS.

The statement was made in the Montreal Correspondence in our March number that Mr. J. O. Marchand, of Montreal, was the only Canadian student of architecture at the Ecole des Beaux Arts in Paris. This is incorrect. In December last Mr. A. H. Chapman, formerly a student in the office of Messrs. Burke & Horwood, Toronto, went to Paris and entered upon a course of study in architecture at the school. Through the courtesy of Messrs. Burke & Horwood we are permitted to reproduce from one of Mr. Chapman's recent letters the following description of the methods of instruction employed at this celebrated institution :

"I am thoroughly in love with the system, and I do not think a better one could be followed, for the first part of it anyway. In getting into the school the architectural subject counts for most, then the drawing, mathematics, modelling, and lastly history. It is necessary, however, to get a pass mark in all the subjects.

The architectural consists in a design on a given subject made under the surveillance of the Ecole officials, and in the limited time of twelve hours. The drawings generally consist of plan, elevation, and section done in pencil and rendered with a wash, for which it is necessary to work out the shadows. The drawing of this design is usually clear, distinct, and, although there is not time to do very careful work in the detail, it is cleverly indicated, and all that is drawn is correct, and all that is wanted on such a small scale (usually about ¼ in. to foot.) This practice of doing the sketches quickly teaches us to be decisive, and to look to the essence of the design. The designs also are rather strictly classical, which is very good, as the study consequently resolves itself into composing, not creating, as a beginner cannot very well create until his senses are trained to the proportion of forms and to the meaning of detail.

For the drawing examination a charcoal drawing from a cast is required, for which eight hours is allowed. This is usually well executed, correct in proportion, line and values in shading. In this also we learn to pick out the essence and get that right. Both these subjects train the senses, and discipline the mind, without in the least cramping the imagination, except perhaps the danger of a student seeing so many strong men believing in a certain style, being afraid to be original, but even that danger is practically done away with, as the work the seniors do in many cases is as original and free as possible. When the students enter the school in the second-class work they still keep on classical lines, but in the first-class concours they are unlimited. Occasionally at the school they have what we call an "esquisse esquisse" which consists of a design worked out at the school in limited time, generally twelve hours, and I do not know if I told you that in all concours the "partie", which means the idea of the design, has to be worked out at school in a limited time and left there ; so that when the judgment is given, the judges have a sketch showing the student's power of conceiving an idea, and a drawing showing his ability in carrying it out.

The examination in mathematics consists in the usual higher mathematics, and that of modelling and history are unimportant and very easy.

The Toronto Architectural Eighteen Club have fitted up their rooms in connection with the Central Ontario School of Art for the use of students. Classes are meeting regularly and work in design is being proceeded with on the lines prescribed by the Educational Committee.

CATALOGUE FOR THE ASKING

CAUSES OF VARNISHING FAILURES.

Newly manufactured varnish often produces a grainy or spotted appearance. The only remedy is to refrain from using such varnish. It must also be noted that the skin which forms on varnish when it is stored in imperfectly closed vessels may also produce the above-mentioned effect, as may pumice dust on the work, or dust collected from the varnish by the air.

Sweating, which principally happens with good fat varnishes, can be prevented by allowing the smoothed surface to dry for a few hours, so that it may sweat before the varnish is applied, and then give it another touch up with pumice. The varnish is apt to creep if there are oily patches on the surface or if it has been touched with wet hands ; but the same effect may be produced by want of skill on the part of the varnisher, as when folds of varnish appear at the edges.

A varnish may often appear like pressed leather, or as if enamelled, if it has been applied in too cold an atmosphere, i.e., below about 70° Fahr. A stripy appearance may also be caused by improper mixing with turpentine, or by too much working with the brush.

Pin holes and pits are produced chiefly by working in too damp an atmosphere, so that the remedy is easily seen. The sinking in of varnish is generally due to faulty preparation of the surface. The color must have a smooth surface to enable the varnish to combine strongly with it. Another cause is found when wood which is not thoroughly dry is varnished. It is a good plan to pour out the varnish an hour before it has to be used, so that gases in it may escape and not make the coats dull.

Varnish flakes off when applied to unsuitable ground, or when the latter is varnished damp. The same thing may happen if the pigment had been applied too thick, or if it is not quite dry when the varnish is laid over it. Too much dilution with oil of turpentine may also cause varnish to crack off.

The appearance of cloudiness or smokiness in a coat of varnish is the result of atmospheric influences during drying. The room must be freely ventilated to make the drying as rapid as possible. A sojourn in damp rooms is apt to give varnish a blue or green color.

Spots left where mud has adhered and been washed off, naturally seen much on carriages, gradually disappear with repeated washing. Varnish blisters either from heat, or on account of the presence of oil under the varnish. The effect of leather and elbow grease in heightening the lustre of a varnish is too well known to require more than a passing allusion.

After hearing the evidence in the action for alleged attempted blackmail brought by Mr. Joseph Wright against Mr. Joseph Sherlock, of Toronto, Judge McDougall decided that from the legal standpoint no threats had been made, and accordingly withdrew the case from the jury. The action arose out of some remarks made by Mr. Sherlock relating to the character of the plumbing work done by the plaintiff in the new municipal buildings, Toronto, for which work the defendant was an unsuccessful tenderer.

EXAMINATION
TO
Qualify for Associateship
IN THE
Royal Institute of British Architects

The Royal Institute of British Architects, desiring to give facilities for those in the Colonies, to qualify by Examination for Associateship in the R. I. B. A., have decided to hold an Examination from June 21st to 27th, 1901, in Montreal. Applications, Fees, and Probationary work must reach London not later than May 5th, 1901. Intending candidates, who must be over 25 years of age, can obtain application forms and copies of the previous examinations on application to

ANDREW T. TAYLOR,
Hon. Secy. R. I. B. A. for Canada,
43 St. Francois Xavier St.,
Montreal.

NOTE.—Those who are members of recognized architectural associations who have passed the regular final examinations appointed by such associations, are exempted from submitting probationary work, but evidence of passing such examination must be given.

FIRE-PROOF GLASS WINDOWS
THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time) ; fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

THE USE OF THE GASOLINE TORCH AND FIRE INSURANCE.

So many serious fires have been caused by the careless handling of the gasoline torch within the past few years, says the Painters' Magazine that the underwriters have become alarmed, and have added a new clause to the policies of fire insurance, forbidding the use of this torch for burning off paint, even though it may be a universal trade custom. Even under the old form of policies it is a question whether the insurance companies can be made to pay for any loss caused by one of these torches, unless special permission to use them is endorsed on the policy. It is therefore wise for any painter who is called upon to do a job of burning off to state the matter very clearly to his customer, and to throw the responsibility entirely upon the property owner, giving him an opportunity to consult his insurance agent before the use of the torch is begun. Unless this action is taken, the painter may find himself in the very unpleasant predicament of being responsible for damages either to the insurance company or to the property owners, for even the plea of trade custom could not be made to hold in any court against a claim for damages resulting from fire caused by a paint burner in the hands of a careless employee. It is better even to lose a job than to be mulcted in damages to such an amount as might sweep away the savings of a lifetime. While the old-fashioned charcoal burner is not so effective as the modern gasoline torch, it is not nearly so dangerous, and when the matter is explained to the property owner, he would doubtless prefer to pay the extra cost of burning off by means of the charcoal burner rather than run the risk of the more rapid but far more dangerous method. As we understand it, the insurance companies object only to the use of gasoline, or naphtha, since the tongue of flame of the gasoline burner is so apt to find an entrance into minute cracks and to set fire to the tarred paper that is used between the inner and outer skin of the modern frame building, and thereby cause a fire that will have most disastrous consequences. It would be well, however, for the property owner to have the opinion of the insurance agent who has written the policies in each particular case, before a painter undertakes to execute any contract for burning off paint.

TWENTY-SECOND ANNUAL EXHIBITION OF THE ROYAL CANADIAN ACADEMY OF ARTS.

This exhibition, which is now being held in the Gallery of the Ontario Society of Artists, King St. West, Toronto, is one of the best representative exhibitions held by Canadian painters that we have had the pleasure of seeing. It embraces the work of nearly all the members, and from this collection we believe will be chosen the works to represent Canadian art at the Pan-American Exhibition. Many of the pictures are old friends, especially those by local painters. The eastern artists, however, add to the interest and enjoyment of the Exhibition. We have two excellent portraits by R. Harris, the president of the Academy, and also one particularly charming thing, "The Banjo Boy." The "Landscape" by Mr. Brymner is forcible and masterly. We have two pictnres from the brush of Horatio Walker, now residing in New York, one of which is a perfect little gem and a rare treat. Another large picture, "The Bathers" by Blair Bruce, residing in Paris, France, is breezy, clever and decorative. Miss Florence Carlyle contributes an interior called "Golden Rod, from the standpoint of light and color an admirable little bit. Homer Watson is ably represented, rich in color, gem-like in quality, but evidently influenced by the old Constable school. A little canvass by St. Charles entitled "Red Man" is a daring and exceedingly clever little piece of technique.

John Hammond, of Montreal, contributes one of his misty dawns, always poetic and sweet, and Maurice Cullen one of his sunny pastorals. In water colors we have two excellent things by Wm. Brymner, of Montreal, and one by a deceased member, Charles Moss, whose removal is most deeply mourned, as he was really one of the most promising young academicians.

Space does not permit of dealing with this matter but summarily. We therefore take the liberty of drawing attention to merely a few of the contributors from the eastern provinces who are not so frequently seen in Toronto. Our local members have been commented on in the past, and are old and highly esteemed friends.

We are glad to announce that Mr. Dyonnet has been elected a member of the Royal Canadian Academy.

NEW CONTRACTING FIRM.

Mr. T. W. Horn, President of the Luxfer Prism Company, has recently formed a partnership with Mr. William A. Illsley, contractor, of Chicago. Mr. Illsley has had an extensive experience in the construction of large buildings in Chicago. The new firm have been awarded the contract for the large hotel to be erected on King street east, Toronto. The contract price is understood to be about $800,000.

NOTES.

A Rochester despatch states that all the stone quarries in western New York producing the famous Medina block paving stones are to be formed into a trust, with a capital of $1,500,000.

A charter has been granted to the Dominion Portland Cement Co., of Wiarton, Ont., capital $250,000, to manufacture Portland cement, bricks, tiles, etc. The provisional directors include David Porter, D. M. Jermyn, both of Wiarton, and John Rowland, Walkerton, Ont.

If mortar is intended for pointing brickwork, a light coloured mortar is composed of lime, putty, yellow ochre, silver sand and copperas, the proportions being regulated according to the desired shade. If the mortar is intended for external plasterwork, a yellow tint is obtained by an admixture of yellow ochre, or yellow oxide, with the material used for the setting coat. A durable yellow tint is also obtained by using a bright yellow sand.

Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.

Our Students' Department.

Attention is directed to the first of a series of articles on Portland Cements, which appears in the Students' Department of this number. Mr. J. R. Gardiner, architect, of Montreal, very kindly offered to prepare these articles for the benefit of students, who will, no doubt, appreciate his friendly interest in their welfare as well as the value of the information supplied. It is hoped that that other architects will follow the example set by Mr. Gardiner, by contributing from their store of knowledge and experience to the needs of the younger members of the profession.

Protection of Buildings from Lightning.

This forms the subject of an enquiry which is now being conducted by a special committee appointed for the purpose by the Royal Institute of British Architects. The committee invite from competent observers data relating to the effect of lightning strokes on buildings, whether fitted with lightning conductors or not. Particulars such as the following are asked for :—Description and situation of building struck, height above sea-level, position with regard to other buildings and high trees, and propinquity to wells ; whether rain was falling at the time, if not, whether rain preceded or followed the stroke, and at what interval ; as to the number of lightning rods on the building, giving position, height above roof, material (both of rod and staples) shape, sectional area, how finished at top and at bottom, condition after flash, &c. ; whether conductor was continuous ; particulars of earth connection : when conductor was first examined and tested ; nature of soil ; the precise nature of the injury to the building ; if any portion was set on fire ; damage to metal work, such as bells, rainwater and other pipes, electric bells or telephones ; distance from conductor of portion of building affected ; materials of roof coverings, and position of gutters and down pipes ; whether conductor was in contact with any other metal ; particulars as to metal-cresting, weather cocks, finials or flagstaffs on the building, stating distance from and the height above conductor ; if conductor was struck, whether damaged portions can be obtained for examination, &c.

Housing of the Poor.

In London and New York, earnest efforts are being made to provide better living accommodation for the poorer classes, thereby making life to them better worth living and lessening the amount of disease, vice and crime. In London, the problem is being dealt with by the County Council, which, as the result of experiments on a smaller scale, has now decided to invest $7,500,000 in the purchase of 225 acres of land on which to build 5779 workmen's cottages in Tottenham, a suburb in the north eastern district. These cottages will accommodate 42,500 persons. The rental will be $1.50 per week for a cottage of three rooms and a kitchen and $2.50 per week for a cottage of five rooms and kitchen.

By special arrangement with the railways, workmen residing in this district, will be carried to and from their place of employment at one quarter regular fares. The enterprise is expected to pay a small dividend. In New York model tenements have been erected by private enterprise to the value of $1,500,000. The results have been so satisfactory that it is proposed to invest $1,000,000 more. These model tenements, while in striking contrast to the overcrowded buildings in which the poorer classes have heretofore lived, and are yielding satisfactory returns to the investors.

An Interesting Legal Point.

The insurance companies holding policies on the Advertiser building, recently burned in Boston, contend that they are only bound to pay the amount of the policies or replace the building with one of identical character. The by-laws enacted since the time of the erection of the burned building, prohibit the putting up of such a structure. The owners of the building claim that the insurance companies are under obligation to put up a structure that shall comply with the existing law. To do this would involve a much larger expenditure than would be required to build a counterpart of the old building. An appeal will therefore be made to the Courts to decide the measure of the companies' responsibility. The verdict will have an interest for building owners and insurance companies everywhere.

THE EFFECT OF FREEZING ON CONCRETE.*

By Walter A. Rogers.

With the constantly increasing use of concrete, questions as to its qualities are continually arising. It has been a commonly accepted opinion among engineers that the building of concrete masonry, especially above ground, during freezing weather is bad practice and one to be avoided if possible. The writer has frequently found it necessary to put in Portland cement concrete footings during the winter months and considerable care has always been taken to protect the freshly-mixed concrete from freezing. There has, however, been a feeling of uncertainty as to the effect of freezing if it should take place before the concrete has thoroughly set.

In order to determine as far as possible by experiment the result of freezing Atlas Portland cement concrete and Louisville cement concrete, which were taken as types of Portland and natural cements, eight 12-in. cubes of each kind of concrete were made and tested as described in the accompanying tables :

The gravel was composed of about two-thirds clean coarse sand and one-third small stones. The crushed stone was crusher-run limestone. The cubes were all made by the same man and those for the same kind of cement were made on the same or on succeeding days. The specimens were moulded in boxes made of 1-in. boards, and left in these until taken out to be broken. Two of the eight cubes of each kind of concrete were mixed with salted water in the proportions of one pint of salt to ten quarts of water. The other six were mixed with ordinary hydrant water. Two of the latter were kept in a warm office until broken ; they were used for purposes of comparison. Four were placed out of doors as soon as mixed in a temperature considerably below zero, and left outside for 28 days, when two of them were broken and two taken into the warm office and left for 28 days more before breaking. The two cubes of each test which were mixed with salted water were placed outside as soon as made, and left to freeze and thaw until broken at the end of 28 days.

Referring to table No. 1 showing the effects of freezing on the Atlas cement cubes, it will be seen that the two cubes which were left in the office, Nos. 103 and 104, developed an average strength at the end of 28 days of over 185,000 lbs.—which was the capacity of the testing machine employed ; but probably the strength of these cubes did not much exceed this amount, as one of them began to fail at that load.

The two cubes which were placed outside in temperature of about 15 degs. below zero immediately after being made, Nos. 147 and 148, developed an averaged strength of 115,000 lbs. The two cubes made at the same time and left out of doors for the same length of time and then kept in a warm room for 28 days more developed a strength of over 185,000 lbs., probably greater than that shown by the two cubes left in the office for 28 days, since no sign of failure by either of these cubes was manifest, indicating that freezing of these four cubes had the effect merely of causing the concrete to harden more slowly than it would have done under more favorable conditions of temperature. The two cubes mixed with salted water and then exposed to the cold for 28 days developed a strength of over 185,000 lbs., probably about the same as that of the two unexposed cubes.

The deductions which may be made from these Portland cement tests are :-(1) Freezing before setting does not seem to injure the Portland cement concrete even if, after having frozen hard, the concrete is exposed to alternate freezing and thawing weather. (2) Exposing freshly-mixed Portland cement concrete to freezing temperature seems to affect its rate of hardening, making it slower, it appears, but eventually the concrete will be just as good as if it had not been exposed to the cold (3) The use of salt seems to largely counteract the effect of the cold in causing slow hardening.

Table No. 2 shows the tests of Louisville cement concrete cubes. It will be seen that the cube left in the warm room, No. 119, and broken at the end of 28 days developed a strength of 43,400 lbs., while cubes No. 153 and 154, which were placed outside in a temperature of 10 degs. below zero as soon as made, showed an average strength of 33,000 lbs. at the end of 28 days. Cubes Nos. 157 and 158, made at the same time as the last two and left out in the cold for the same length of time and then kept in a warm office for 28 days longer, had an average breaking strength of 52,500 lbs. The two cubes mixed with salted water and exposed for 28 days developed a strength of 35,000 lbs., being but little more than those treated in the same way and mixed with fresh water.

The same deductions may be made from the tests of Louisville cement concrete as from the Atlas tests, with the exception that the use of salt seemed to have had little, if any, effect on the strength of the cubes exposed to the cold. The fact that the extreme cold seems to have merely caused the hardening of the concrete to proceed more slowly than under more favorable conditions of temperature is brought out in a marked manner by the fact that the cubes left out in the cold for 28 days and then kept inside for 28 days developed a strength of 20 per cent greater than those which were kept inside for 28 days and then broken.

*A paper read before the Western Society of Engineers of U. S. A.

A certain retaining wall was built of Louisville-cement concrete, faced on the top and front with Portland cement mortar. The weather was quite cold part of the time while the concrete was being mixed, and part of it must have frozen before setting had entirely taken place. The 2-in. plank form was left in position until the Spring, and about 4 in. or 5 in. of sand was placed on the top of the wall. In removing the form last Spring it was found that the body of the concrete, to all appearances, was in good condition. About six inches from the top however, the Portland cement facing was badly cracked and by sounding occasional spots were found both in the Portland cement facing and in the back of the wall, where there seemed to be a thin loose shell. Evidently these are surface defects, and the wall itself appears to be in good condition.

The writer believes that the foregoing tests indicate that concrete work with cement possessing qualities similar to those tested may be carried on safely during moderately cold weather by using proper precautions, such as warming the materials and the water, and by so protecting each layer of concrete that its top shall not freeze before the next layer is laid.

[Note.—The temperatures recorded are Centigrade.

THE GLASGOW EXHIBITION.

The site of the Glasgow Exhibition comprises 73 acres intersected by the River Kelvin. The buildings, which were designed by Mr. James Millar, I.A., of Glasgow, cover an area of 20 acres. They are divided into three groups—the general industrial section, the machinery hall, and the grand hall for entertainments. They are designed in the Spanish Renaissance style, oriental coloring, the leading feature being the great dome 200 feet high and 80 feet in diameter, with four accompanying towers, each 160 feet high. A balcony 400 feet in circumference and 25 feet wide forming a promenade, surrounds the dome at a height of about 100 feet. This balcony is reached by powerful lifts and wide stairways. A colonnade 200 feet long and 80 feet wide with floor of ornamental black and white marble, leads to the main entrance beneath the great dome.

Next to Great Britain, Russia occupies the largest amount of space. A grant of £30,000 was made by the Russian government, for the erection of buildings which are all designed in the old Russian style, put up by Russian workmen, mainly with the aid of short-handled axes.

A USEFUL CEMENT TESTING DEVICE.

Mr. W. F. Goreham, an English cement works expert, has patented a device called a "Flourometer" for separating the flour from residue of cement, thus enabling the proportion of cementitious matter in the cement to be exactly arrived at. In this device, which is intended to furnish a means of test of quality of cement to architects and contractors, and other users of cement, air under a certain fixed pressure is supplied by an aerometer attached to the tube of the flourometer. The cement is placed, in a fixed quantity carefully weighed, into a conical glass, and a central tube is brought into it, with the bottom edge cut in a particular way. Air is then forced down the central tube, and rising up through the cement, lifts through the vertical tube all that is light enough to be lifted by its current, which is then deposited in a special settling chamber. About 2 to 3 per cent. of the flour is lost, but the residue always remains intact to be weighed for proportion.

The first stone of Cologne Cathedral was laid on August 15, 1248, and the body of the edifice was not opened until August 15, 1848, 600 years later to the very day. It was not, however, until August 15, 1880, that the splendid structure was finally completed, having thus occupied in building the "record" time of exactly 634 years.

Branch Office of the CANADIAN ARCHITECT AND BUILDER,
Imperial Building.

MAY 6TH, 1901.

THE NEW BUILDING BY-LAWS.

"The Montreal Building By-law of 1901" was passed by the City Council on the 4th February, and thanks are due in the first place to the committee of the P.Q.A.A., who about two years ago at an immense amount of labour studied the question and wrote out the text of the By-law, and secondly to Alderman Hart and those who worked with him for getting the by-law passed after having laid on the table so long.

We can congratulate the city in now having, in most particulars at any rate, a Building By-law that is workable and up-to-date and we trust that Mr. Chausse, the Building Inspector, will see that the various clauses are carried out. Mr. Chausse has already made great changes in his Department in the short time he has been in office and we are glad to be able to report that this Department is, at the present time on a good business-like footing. May it never be allowed to again sink to the level from which it has at last been raised, is the hope of all those interested in the City's welfare.

The By-law has been printed and it would be well for all architects and contractors, who have not already obtained a copy to do so and make themselves conversant with the various changes.

There is one good clause to which we would especially like to draw attention viz:—No permits shall be given for the erection of 3rd class buildings within the following districts bounded as follows:—

On the N.E. by Delorimier Ave., Craig and St. Andre Sts.
" " N.W. " DeMontigny, St. Urbain, Ontario, Berthelet St. and Burnside Place.
On the S.W. by Mountain and Record Sts.
" " S.E. " River St. Lawrence.

The text of the By-law was published in the CANADIAN ARCHITECT AND BUILDER for November and December, 1899, and but few alterations have been made. The portion referring to Plumbing has not been included, as it is intended to make a separate By-law of this part.

THE P.Q.A.A.

The Vice-President and Montreal members of the Council were "At Home" to the members of the Association on April 25th. Mr. Venne gave a very interesting lecture on the Certosa di Pavia, which was well illustrated by photogravures of different portions of the buildings, one of which showed the similarity between its entrance gateway to that of the Ponce de Leon Hotel in Florida erected some few years ago from plans made by Messrs. Carriere & Hastings.

The lecture was preceded by some capital selections on the violin as well as one or two songs, and Mr. Doran made a few remarks in reference to the lecture, saying that architects in the rush of every day practice had not the time necessary to work out the details of carving, etc., in such work as shown on the board and that he would like to suggest that they should be allowed to call in an artist to aid them in this class of work. This seems to us to be a dangerous idea to advance as if architects have to call in the aid of an engineer to draw out their steel construction and an artist to help them in their carving and mouldings that are a little beyond those used in every day practice, we are afraid that clients will begin to wonder what an architect is supposed to know beyond or above a contractor.

An architect from our point of view should be an artist with the practical knowledge necessary to be able to carry out his dreams on a sound constructional basis.

At the request of some of the members of the Association, a special general meeting has been called for May 8th to consider the alterations recently made in the "Schedule of Charges."

LOCAL PROSPECTS.

Nearly all the local architects appear to be busy and a large amount of work has been tendered on during the past month. The chief topic of conversation among architects at the present is the giving of the contract for the new Bank of Montreal building to Messrs. Norcross Brothers, of Worcester, Mass., and New York. Naturally all persons interested in the welfare of our Canadian builders are feeling sore at seeing the best contract given out so far handed to an American firm, even though it is one of the standing of Norcross Brothers. We regret very sincerely that the Directors saw fit to give the work to a firm not residing in this country, as their action is apt to be misconstrued as a kind of slur on the capabilities of our local men. We believe that the decision of the Board was only influenced by dollars and cents, and as the American firm was the lowest tenderer the contract was awarded to them. We feel, however, that Americans rarely, if ever, show us any reciprocity in this sort of thing and when it is a public body such as the Bank of Montreal, who are so bound up with the interests of the country, and are, we might say, a national institution built up out of Canadian enterprise, it seems a wrong policy on their part to pass by Canadian contractors. A building of this class is surely not above and beyond our contractors, for if such is the case, and we do not for one moment think so, the sooner they look into the matter the better for their own and their country's reputation. In the matter of cost, we can imagine that as certain materials must come from the United States that American firms may have been able to make better terms in certain cases than our local men—"Alas! now this way and now that turns fortune's wheel." Some of the other buildings already tendered on are: The new building for the Royal Insurance Co., which will form an addition to their present building on Place d'Armes, from plans by Messrs. Hutchison & Wood; a large factory for Messrs. Gault Brothers, on Hay Market Square, in the office of Messrs. Finley & Spence; College Buildings for the Grande Ligne Mission at Grande Ligne, from designs by J. Rawson Gardiner, and a warehouse for Jesse Joseph, Esq., to replace the buildings recently burned in the Board of Trade fire at the corner of St. Peter and Lemoine streets. This is the first attempt at rebuilding in the burned district, and the men are now clearing away the debris in the cellars of the burned structure. Mr. Coristine has had plans prepared for a large office building to replace his buildings burned in this district, but no contracts have so far been given out. The Council of the Board of Trade have done nothing definite, so far as we are able to ascertain, in preparing plans, though it is generally considered that some decision will have to be arrived at shortly. The C.P.R. Telegraph building is now nearing completion but the Grand Trunk Building does not show signs of being completed before the autumn. There should be no good draughtsmen idle at the present time as from word received both from New York and Chicago, there is great scarcity of good draughtsmen in both those cities.

THE PAN-AMERICAN EXHIBITION.

No doubt many of our local architects are looking forward to a trip to the Buffalo Exhibition. The various buildings have all been designed by eminent architects, and as colour has been extensively used in the general scheme, the result, no doubt, will be interesting. Colour has generally proved somewhat of a "bete noir" to architects in a northern atmosphere so that it may lead to further endeavors in this line, but so far any attempt beyond what is sometimes called the sombre has usually been unsuccessful, even if not verging on the disastrous. The Exhibition was to have been opened by May 1st, but the weather has been very unpropitious the last month so that the opening day has had to be postponed. A list of the chief buildings with the names of their designers is given here, as it may prove of interest to those considering a trip to the Exhibition:

Liberal Arts and Agriculture .....Shepley Rutan and Coolidge.
Horticulture, Forestry and Graphic Arts..Peabody and Stearns.
Machinery and Transportation.....Green and Wicks.
Administration Building.....Babb, Cook and Willard.
Mines and Ethlogy.....George Cary.
Electric Power.....Howard, Cauldwick and Morgan.
Landscape Plan, etc .....Carriene and Hastings.

The board also retained the services of Mr. Carl Bitter for the sculpture and Mr. Turner for the mural paintings and decorations

These Exhibitions seem to be annual affairs now and soon we will be able to use them as Experimental Stations for our architects.

STUDENTS' DEPARTMENT.

NOTES ON CEMENT.

By J. R. GARDINER.

[All Rights Reserved.]

The following notes on "Cement" are intended as a short synopsis of what others have said with an attempt to place them in a clear and concise manner capable of being understood by the student and not in any way as an addition to the already voluminous literature on this subject.

CEMENTS.

As cement can be considered one of the most important building materials that an architect uses and furthermore one that is being used more extensively every day it is necessary that the student of architecture should understand in outline at all events the chief distinctive characteristics as well as the mode of manufacture of the various types in order that he may use them intelligently.

The basis of all limes and cements is Carbonate of Lime and in order that lime may contain hydraulic properties it is necessary that it be chemically combined with some form of Silica—usually clay, which is a hydrated Silica of Alumina. It is largely the proportions in which these two materials are mixed that constitutes the type of cement to which it will belong. There are two heads under which cements are usually classified:—

1. NATURAL CEMENTS.
2. ARTIFICIAL CEMENTS.

Under the heading "Natural" cements is usually included all so-called Roman cements as used in England, the hydraulic limes as found in France and Belgium, and the natural rock cements used so extensively in America.

Let us first take the industry in America:—

1. THE NATURAL CEMENT INDUSTRY IN AMERICA.

Large deposits of Hydraulic Limestone, capable of producing good natural cements, are found in the United States, chiefly in New York, Maryland, Pennsylvania and Kentucky—and also in the Province of Ontario in Canada.

The natural cements produced from these limestones differ from hydraulic lime in that they do not slake at all, their bulk and temperature remaining the same during both mixing and setting. They also set very rapidly either under water or in the air. The most distinctive feature of these cements is the marked difference in the amount of magnesia they contain and they are on this account usually divided under the two headings:

1. Lime Cements or those containing from 2 to 4% of magnesia.
2. Magnesian Cements or those containing from 12 to 30% of magnesia.

The larger part by far of the deposits worked come under the latter category as they contain all the well known "Rosendale" brands. These magnesian cements set and acquire strength rather more slowly than the lime cements but eventually equal them. They do not heat on mixing with water and do not withstand frost as well as the lime cements when first mixed.

The lime cements gain their strength very rapidly but they have to be very carefully prepared as they have a tendency to heat if too rich in lime and to blow if too strong in silicates.

By the following tables it will be seen that the chemical composition of the various brands found in different parts of the country varies considerably. Great care has to be used also in the same quarry as different strata produce varied results so that analyzing has to be resorted to continually if the best results are expected.

	Rosendale.	Milwaukee.	Louisville.	Fort Scot.	Round Top.
Ca. O.	34.64	33.40	46.64	49.80	45.66
Mg. O.	14.82	22.60	12.00	12.20	2.80
Si. O_2	16.48	13.80	20.40	17.60	21.70
Al_2O_3	10.93	4.00	4.76	4.00	8.30
Fe_2O_3	4.65	2.80	3.40	5.00	4.15
$Na_2O + K_2O$	1.80	2.50			
SO_3	1.04	2.59	2.57	2.04	1.30
$CO_2 + H_2O$	4.50	9.50	6.75	4.50	8.20
(Silicates undecomposed.)	12.40	11.20	3.74	4.20	8.00

The "Rosendale" cements, of which there are several different brands, are the best known natural cements in America. They are the standard of the magnesian variety, and form nearly half of the total production of natural cement in America. The "Round Top" is usually taken as the typical lime cement. The supply is somewhat limited, and is therefore chiefly used in its own district, supplying Washington, Baltimore and the more southerly cities. The manufacture of these cements is similar with either variety. The hydraulic limestone is usually burned in a draw kiln which contains enough stone to make from 400 to 600 barrels. The stone and coal is laid in alternate layers, and is usually drawn twice in twenty-four hours; but this depends largely on the variety of stone. It is carefully sorted, and all under-burned portions and clinkers are then removed. In the case of lime cement it is then either sprinkled with water or steamed, in order to slake any excess of lime. It then passes to the mill, where it goes through the process of being crushed and carefully ground, and in the better cements screened.

The cement is then packed in barrels, which in the Eastern States contain 300 pounds, while in the West 265 pounds is the usual standard. In regard to fineness, which in late years has been receiving a good deal of attention, both from engineers and manufacturers, the best cements are expected to pass the following test:

Residue on 200 mesh, 10 per cent.
" 100 " 6 "
" 50 " 2 "

Although a large proportion of cements tested will no doubt be found to leave 20% residue (at least) on a 200 mesh. As to strength and reported tests of natural cements one is as far from arriving at a certain goal as in Portland cement testing. There are so many pitfalls one can stumble into in testing cement that one is apt to feel disheartened with the numerous tests showing almost any result one could wish. However, the following table prepared by Mr. Clarke for the Boston Main Drainage work from over 25,000 tests and made with great care to show the result of comparison between Natural and Portland cements will no doubt be of interest:

NATURAL CEMENT.

	Neat	1 cement to 1 sand	1 cement to 2 sand	1 cement to 3 sand
7 days	92	56	24	14
28 days	145	116	60	35
6 months	282	190	125	80
12 months	290	256	180	121
PORTLAND CEMENT.				
7 days	303	160	126	95
28 days	412	225	163	140
6 months	468	347	279	198
12 months	494	387	323	257

These tests shew the average of several brands and give a fair idea of the proportional value of the two varieties.

The American Society of Civil Engineers gives the following table as approximate tests of the two cements, natural and artificial:

NATURAL CEMENT.

	Neat.	1 Cement 1 Sand.
7 days	60 to 100	30 to 50
28 days	100 to 150	50 to 80
1 year	300 to 400	200 to 300
PORTLAND CEMENT.		
	Neat.	1 Cement 3 Sand.
7 days	250 to 550	80 to 150
28 days	350 to 700	100 to 200
1 year	450 to 800	200 to 300

The above tables shew that, as a rule, taking equal quality in both natural and Portland, one part of natural cement and one of sand is equal in ultimate strength to one part of Portland cement to three parts of sand. The natural cements set quicker, but do not at first attain so great strength.

The color of natural cements varies considerably from a light buff through a gray resembling Portland to a darkish brown as most Rosendales. This variation in shade is due to the proportion of oxide of iron contained in the stone, and has in no way any effect on the value of the cement, although two barrels of the SAME brand of different shade would probably indicate that the lighter one was of unburned rock.

In regard to weight, the American Society of Civil Engineers in their report on cement tests, say: "The relation of the weight of cement to its tensile strength is an uncertain one. In practical work, if used alone, it is of little value as a test; while in connec-

tion with the other tests recommended it is unnecessary, except when the relative bulk of equal weights of cements is desired." Fine ground cements are lighter than coarse ground, but under-burned cements are also lighter than well burned, so that it is hard to depend on weight alone as a sure test except in conjunction with other means of testing.

The large quantity of these "Natural" cements used in America has made this material a most important one to both architect and engineer, and a cursory glance at the extent of the industry will therefore no doubt be of interest.

There were, in 1898, 76 mills manufacturing natural rock cements in the United States, 29 of which were situated in New York state, turning out chiefly a brand of "Rosendale."

This cement derived its name from the township of Rosendale, Ulster county, New York. The other plants are situated in almost every other state, due chiefly on account of the cost of shipping being high in proportion to the cost of manufacture. The chief producing states are Maryland (where most of the lime cements are made), Pennsylvania, Kentucky and Indiana, the total output being over 8,400,000 barrels, of which New York state has nearly one half to her credit.

Canada in 1900 produced 125,428 barrels of natural cement all of which was manufactured in the province of Ontario where there are 4 separate plants.

2.—THE NATURAL CEMENT INDUSTRY IN EUROPE.

In Europe the natural cement industry is carried on chiefly in Great Britain, France and Belgium.

Natural cements in England are made from cement stones or nodules found in thin strata among limestone and also in the London clay. In 1796 Mr. Parker took out a patent for what he called Roman cement, and which has for this reason sometimes been called Parker's cement, and was made from calcining these nodules from the London clay. These natural cements are generally termed after the name of the district where they are manufactured, as "Sheppy," "Harwich" or "Whitby" cements, and usually contain from 30 to 40 per cent of clay. Medina cement is made from the septaria found in Hampshire and the Isle of Wight, as well as from those dredged out of the bed of the Solent. It is generally considered superior to most Roman cements. It sets very rapidly, and is of a light brown color.

A large proportion of the material used in the manufacture of natural cements in England is unfortunately very variable and irregular, so that the results obtained from their use have not always been satisfactory, and Portland cements have to a large extent for this reason driven the natural cements out of the field.

At Boulogne, which is the chief centre of the industry in France, there is a soft deposit which can be excavated with pick and shovel, and consists of 22.6 per cent of clay and 76 per cent of carbonate of lime. It therefore makes a sufficiently hydraulic material to be termed a very slow setting hydraulic cement.

THE ARCHITECTURAL STUDENTS' CLUB.

For some time prior to the formation of this Club, there had been a growing feeling amongst many of the Toronto students, that something was needed to draw them together, and to promote some enthusiasm in the different branches of architectural work, especially design.

When, therefore, Mr. D. W. F. Nichols, who is now president of the Club, proposed its formation, he met with vigorous support from a majority of the students. On his invitation a number met on the evening of Jan. 29th, 1901, at the office of Messrs. Burke & Horwood, 28 Toronto street, when it was finally agreed to form a club to be known as "The Architectural Students' Club." The following officers were elected: President, D. W. F. Nichols; Vice-President, A. H. Russell; Sec.-Treas., A. M. Weir; Committee, J. M. Crysler and H. A. Payne. It was decided to meet every Tuesday evening to have competitions and talk over any matters of interest.

Several meetings were held at which a few new members were enrolled, but when studio work commenced it was found impracticable to meet on Tuesday evenings, as some of the students attended the studio of the O.A.A. and others that of the T.A.E. Club. In view of this it was decided to meet on Saturday evenings, and through the generosity of the O.A.A. their rooms at 96 King street west were obtained for that purpose. Several professional men consented to address the Club on different topics, which greatly added to the interest of the gatherings.

This season has been to a great extent experimental to the Club, but its officers and members feel fully satisfied that it has accomplished its object, viz., the creating of an enthusiasm in the work and a stronger spirit of fellowship amongst the members.

The lectures given were very interesting and much appreciated by the members of the Club, and the committee expects to have an interesting programme for next fall.

MANITOBA CORRESPONDENCE.

WINNIPEG, MAY 13, 1901.

The "Free Press," of this city has of late been publishing in its columns extracts from the "Free Press" of 18 to 20 years ago. In one of these extracts the writer's name appears in an architectural connection with some buildings of that ancient time. As we look back, what great changes have taken place, what wonders time has wrought, and how the small and scattered city of that day has grown and grown till it now is a good city to dwell in, full of life and progress, where all the comforts of life may be obtained and at no great cost either. The crude store and warehouse of frame or logs has given place to the handsome and palatial shop and the solid and substantial wholesale warehouse; the small cottage or humble home without fence, garden or trees is now exchanged for the comfortable and picturesque home with all modern comforts or the stately residence rearing its well proportioned outline amid the forest trees of by-gone days, or the flower beds and well kept grounds of more modern times. We may ask why is this? and the answer comes back that Winnipeg, Manitoba and the Great North West does now, and will more so in the near future, occupy a most modern place and wield a mighty influence over the prosperity, progress and grandeur of our noble Dominion.

In this procession architecture takes a prominent place, for is not architecture beauty of outline, stability of construction and utility of arangement? As our cities grow in size and richness, and the country takes its place in the functions of the world, architecture will help to lead the way; it has done so in the past, it will do so more in the future. Is it not well then to acknowledge its power, admire its beauty, and note its progress?

In this city of the plains we are making substantial progress, and the year has opened briskly in the building trade; many structures are in course of erection and many more are spoken of. Of a truth in the spring time we are very likely to put on our magnifying glasses and things and times appear greater than they really are. From the present outlook, there will be work enough in all departments of the building trade, but not such as to warrant a large influx of artisans. Our architects and contractors are not idle, but we may say that their hands are not full, and from the architects' standpoint we may remark that more than one could have found time to design and arrange the drawings for the buildings which have been placed in the hands of outside architects. We think there could be found here architectural ability enough to design and carry out any building which has been erected in this city or Province.

Could our architects have the freedom to use the material and money which we presume has been placed at the disposal of our outside brethren, we venture to say, they would have achieved good results from the use of the same, both as regard beauty, stability and utility. While this holds good in regard to our Canadian architects it particularly applies in the case of commissions placed in the hands of a foreign architect.

An architect from Minneapolis has designed an apartment building for which the excavation is now being taken out on McDermot avenue. While we have not a word to say against this gentleman either as an architect or a gentleman, still we think our citizens might have placed their commission with some of their fellow-citizens in the architectural profession without disadvantage to themselves or to our city.

This incident has a wider range and a greater influence than might at first appear. If we wish to foster arrhitecture in our midst and encourage national architectural advancement, we should be ready to employ local talent where it is obtainable.

In regard to apartment buildings, we may add that there are several now in the city and there seems to be a demand for such accommodation. Our long winters no doubt are a factor in deciding the question of being housed in buildings of this character.

While these buildings are to a certain extent public, we think it should be the aim to make them as private as possible. In one instance to which we will refer, The "Avalon," on Notre Dame avenue, this has been accomplished by providing a private hall

(Continued on page 115.)

SKYLINE.*

BY HASTWELL GRAYSON, B.A.

Many many years ago Sir Walter Scott's poetic fancy led him to advise intending visitors to Melrose Abbey to "go visit it by the pale moonlight." There is a tradition that he did not practise what he preached, for on the only occasion when he went to "view fair Melrose aright" a passing cloud obscured the moon altogether. But however that may be the idea in the poet's mind seems to have been that in a strong light the abbey lost some of its charm. Stripped and ruined, roofless and ivy-clad, the architecture had perished and little remained except sentiment and a skyline. The buildings which we build to-day are not likely to have much sentimental value in our lifetime, but nearly all can have a skyline from the commencement. Scott is right—a skyline, like sentiment, has greatest power in a pale light. Defects arising from poor detail, meaningless features, and the poverty of materials, are gradually lost as the light fades, but the outline becomes more manifest. So true is this that Ruskin advises the young architect to try and conceive his buildings "as the dawn lights them and the dusk leaves them."

Except indirectly, the ordinary text-books hardly allude to the importance of skyline, and I cannot find that anyone has ever tried to analyse the why and the wherefore of an effective silhouette. I propose after tracing the influence of the earlier and greater styles of architecture in outline to venture on a few theories for which I cannot quote any authority.

Mr. Ingress Bell has pointed out that the ancients for various reasons paid little attention to skyline. The earlier Egyptians were content with mass, and were satisfied if their buildings were impregnable to time. Later they devoted much time to colour, while still chiefly relying on mass. The Greeks, perhaps consciously, kept their outlines exceedingly simple in order that nothing might detract from the sculpture and detail. The pediment was their sole concession to outline. The Romans went a stage further; they invented the circular plan, which soon led them to build domes. But they designed them to suit the interior without caring apparently how clumsy the exterior might appear. The first really conscious efforts to obtain good skyline are found in Constantinople, but whether this is the work of Romans or Turks I cannot say. The fleche appears to be the part of Hadrian's design; yet, on the other hand, the minarets adjoining the church look like later additions. These additions give much finish to the composition, and the height of the minarets counteracts the heaviness of the domes and semi-domes. This combination was perfected by the Turks in Cairo, where the minarets were made part of the church itself, and not merely adjuncts.

The Christian architects of the Middle Ages worked on entirely original lines. They made a belfry (or rather a bell-tower) an integral portion of their design, secondly, they allowed the exigencies of their construction to become manifest against the sky, and thirdly, they provided their buildings with roofs that were distinct from the vaulting. Perhaps the most important point is the second one; to counteract the thrust of the vault they built pinnacles and parapets, which gradually became the dominant features in the outline. In the later days of Gothic art the roof was entirely lost to view and the skyline resolved itself into rows of small pinnacles, above which soared the spire, itself but a pinnacle, of a larger and more elaborate character.

The Renaissance brought another change. As Mr. Bell says "the Cathedral of Florence and its unrivalled campanile are amongst the most lavishly ornate buildings in the world, but their enclosing lines are simple and severe Only on the summit of the vast dome does the almost universal instinct assert itself in a delicately designed lanthorn as FINISH."

At this period architecture completely changed its character. Throughout the Middle Ages it had been the handmaid of religion; it now became the servant of the people. The labour, the genius and the energy which had been lavishly devoted to the service of God, and to those who proudly claimed to be His earthly representatives, were diverted and made to minister to human wants and comforts. A new feature, infinitely more influential than the pinnacle, became universal. How the ancients warmed themselves, or indeed whether they ever were warm in winter, is a mystery to-day. We know that they had vast kitchen fires, we also know that, except where smelting works existed, the forests supplied fuel enough for the wants of the people. From the sixteenth century the use of the flue gradually spread downwards from the king's palace until to-day almost every room that is built is signalled above the roof by chimney and pot. In the course of centuries the architectural genius of the world has practically conquered the difficulties of grouping flues and ornamenting the stack containing them. Future ages have but one task left—that the crowning one—the chimney-pot.

First let me deal with the old adage, "a spire for a plain and a tower for a hill." It is an excellent piece of advice, but, like the old copy-book maxims, it does not go far enough and leaves the half untold. I should like to expand it thus: All buildings—and especially churches, which are generally isolated—are affected by their environment, and a contrast with their natural (and in a less degree with their artificial) surroundings is most likely to prove successful. Let me cite two instances. Have you ever rowed across one of the English lakes and noticed the old cottages and farm-houses that here and there border the banks? They are very squat and square, have no bay windows, the roofs are covered with large stone slates laid to a flat pitch, there is very little light and shade about them; and yet they look very well. Again, have you ever walked down Princes Street, Edinburgh, and noticed the happy effect of the National Gallery with its long low flat roof? In each case the success is due to contrast. The fells that cluster round the lake and the little promontories and tiny bays that make the shore provide a feast of varied beauty in which the farm-houses, through no effort of their own, are included. If their builders had had a little more ambition they would have tried to compete with Nature, and failed. Ruskin, who as a young man loved to lay down the law with many superlatives and much alliteration, ventures to assert that "a single villa will often mar a whole landscape and dethrone a dynasty of hills." In the second example mentioned the long roof of the gallery helps to emphasise the rugged grandeur of the castle and, on the other side, the height and gracetulness of the Scott Monument.

A tower, because it has a simpler outline than a spire, shows a greater advantage where Nature is bolder. A spire looks best standing by itself in a plain

*A paper read before the Manchester Society of Architects.

high above the tree tops and roofs. As a general rule, the eye in a flat country is grateful for every kind of landmark, towers and spires, windmills and trees. In Liverpool we have an excellent example of how even a factory chimney can give a focus to an otherwise dull landscape. The north end of the town, as seen from the river, presents a monotonous line of warehouse roofs rising steadily one above the other as they recede from the river—so monotonous that the Vauxhall chimney is a most welcome relief.

The value of a contrast in skyline is very curious, because the exact opposite is the rule with materials. Nothing looks worse in a rocky country than red bricks (except red tiles), and half-timber work is generally fatal where trees are rare.

My second theory is almost a corollary of the first. It is this: Where two or three long lines meet, it is well to emphasize the point of intersection. By long lines of course I mean such as are seen in perspective: the lines may be caused by the ground, by the walls, or by the roof. This is the reason why a finial helps nearly all gables, whether they have bargeboards or copings, why a fleche sits so nicely at the intersection of several roofs, and why a turret in the corner of a quadrangle appears so snug and appropriate.

But nowadays in ordinary practice we depend for our skyline almost entirely on chimneys. Partly because the use of cut and moulded brickwork has become so general, and partly because clients are now most outspoken about downdraughts, chimney stacks have of late years been growing in height. For efficiency and for economy they are best when built on the ridge; not on the eaves. For these reasons alone they would naturally appear to greater advantage. Chimneys rising direct from the eaves, unless attached by a gusset roof, to the main roof, look unnaturally thin and weak, especially if "supported" by an iron tie. The effect is much improved if on plan they project considerably. A good building can be spoilt in many ways by its chimneys. They can be too numerous, which suggests bad planning; they can clash with other features and make the outline confused; they can be too high, which makes them look extravagant and the rest of the building too small; and—perhaps what is the worst of all—they can be made too small, a fault which leads to those fearful objects known in the trade as patent cowls.

I have a few illustrations of most of these points. The Gothic mansion at Narrow Water exemplifies the reserve of my theory; there are no long lines in the view, therefore the architect worked on the principle that "many a mickle makes a muckle," and emphasized the intersection of all his lines; and to make matters worse he has made a special feature of every single flue. The result is a perfect jungle of pinnacles and turrets, chimneys and finials—an awful waste of money and an architectural failure.

The exact opposite is seen in the sketch of the Nunnery at Salford Priors. There is such an absence of chimneys as to give the house the appearance of being uninhabited. Perhaps the nuns have no fires; in any case, they must find their home rather chilly, as it is built on the principle "of Hardwick Hall, more glass than wall."

An almost perfect skyline, to my mind, is that of Fytton Manor House. If it has a fault it is that the main roofs do not mitre on the same level. The charm of the contour appears to arise from the happy distribution of the parts and not from the parts themselves. Each one leads upward and onward to the next. Even the conservatory seems to fit against the gable and help the length of the facade.

The cottage at the Godstow old bridge follows somewhat similar lines. A chimney marks each end of the ridge; on one side it is built in and almost hidden by a low gable, while on the side shown in the photograph the chimney boldly projects, and is buttressed by a hipped lean-to roof. The whole makes a very complete and satisfactory outline, which gains very greatly by being duplicated by reflection in the river. That is a point which should be borne in mind by anyone designing a building which will adjoin a sheltered piece of water.

A further instance of a chimney successfully completing a ridge is seen at the Hall at Balliol. The flues from the men's rooms adjoining are incorporated into the end wall of the hall, and serve to emphasise the point where the roof meets the coping—a point which would have appeared characterless without them, for no finial could have finished a gable of that size. The bareness of the other end is masked by a gable over the high table bay flinked by the chimneys from the kitchens.

The sense of bareness which Balliol avoids is very noticeable in the Rathhaus at Molsheim. The apex stones and finials on the gables are lost in the vast expanse of roof. The coping also is far too thin, the result being that this great roof, which from its very size should have been commanding, becomes featureless and disappointing.

My third point is the value of a complimentary feature. This is perhaps most noticeable in Classic work. Think of the great dome of St. Paul's and the two western towers: how much they help one another and assist us to estimate the size of the dome. The source of the harmony lies in their resemblance. We call one dome and the other tower; but they both have a domical outline and are unmistakably parts of the same building even when supervening roofs hide any connection between them. Without these western towers the cathedral would have sunk to the level of several well-known buildings, where the dome is everything and the church only the support.

A large round tower gains very much if a turret clings to its side. The French, especially about the year 1500, made a frequent use of this form. If a tower was unsuited to a turret, they always build a second tower near, as at Amboise and Azay-le-Rideau. In the Inglinger Thor Stendal we have another treatment. Here the circular tower does not sit very comfortably on the square base, but it would have been infinitely more out of place without the angle turrets.

Another example of a complimentary feature of a rather different kind can be seen in houses of the F plan—the plan in which a small gable with a slight projection is placed in the middle of the facade and a larger and deeper gable near the end. In an open site the F plan is much more likely to give a good outline than the E, of which the architects of Elizabeth's time were so fond. Yachting men may perhaps agree with me that a yawl looks more dainty and complete and even larger than a boat of the same size which has only one mast.

My last theory is that the vertical portion of an outline should be kept as subordinate as possible. Vertical features are of course, necessary, often constructional, but if possible they should not be prominent on the skyline. Nature provides us with an example in the stem of the larch tree, Scotch fir, and many others, but she generally contrives to batter the lowest portion and to conceal the upper. I have already pointed out how the conservatory at the Nunnery and the lean-to at the Godstow cottage complete the picture and provide a gradual finish at the base, which is almost as important as a definite feature at the apex. The base to Cæsar's Tower at Warwick Castle is almost double the size of the vertical portion. Mr. H. W. Brewer, in those wonderful architectural compositions which he has been publishing for the last thirty years, gives many instances of excellent skylines, but they are all of the upward and onward type: vertical features he has in plenty, but not against the horizon. Mont St. Michel, that grand personification of the church Militant, has hosts of towers and buttresses which rise sheer up to giddy heights, but with the exception of a small portion of the piers against the great Hall of the Knights, the sublime outline is not the result of high walling. The effect of too much vertical outline can be seen in the Palazzo Vecchio at Florence, a building whose tower fits on the main block like the shaft on to the handle of a T-square.

This is as far as my theories carry me. To recapitulate:—In order to obtain a good skyline, it is well to have a marked contrast with the natural and artificial surrounding; to emphasize the intersection of two or more long lines; to provide a complement to any strongly-marked feature; and to take care to keep the vertical portion of the outline as subordinate as possible to the inclined.

I endeavored to satisfy myself that a dormer should have a sharper pitch than the main roof on which it rests, but after some consideration I came to the conclusion that it depends on how much of the main roof is visible. The larger the roof the steeper the better. The dormers may follow the same slope or they may not; in either case they can fit very snugly, provided they are not too long. A very steep dormer which hides too much of the main roof is like a man with a big nose and a receding forehead. It seems to show an unnatural proportion, curious, perhaps, but not intellectual. We often see dormers of too large dimensions or too near adjoining dormers. That is another instance of failure in proportion. The castle at Hameln has four very large and elaborate dormers which can just find room to balance on the eaves without elbowing each other off. The main roof is quite lost, with the result that the skyline becomes as crowded with large features as that of Narrow Water is with the chimneys and pinnacles.

I remember hearing a story that a pupil once asked Mr. Norman Shaw what pitch he should make a dormer. Mr. Shaw sketched the dormer in freehand. The pupil measured it and finding that the angle was 51 deg. delighted Mr. Shaw by telling him that it was exactly the same as the Pyramids. The angle of the Pyramids is generally considered to be the acme of perfection—for a pyramid; but it was a mere coincidence that Mr. Norman Shaw's dormer should have the same angle.

One of the blessings for which we have to thank the Gothic revivalists is the reintroduction of the gable. The eighteenth century was all for cornice and coping and a featureless skyline. Pediment is all very well when seen in full elevation, but as to suit that point of view the pitch needs to be very low, the effect is lost in acute perspective. So enamoured however were our great-grandfathers with this flatness that it is very doubtful whether there exists a gable that is more than sixty and less than a hundred years old. So many English towns were rebuilt during the age of the hip and coping that I hardly know an English street of gables, although before Queen Anne lived and died the continuous row was invariably the rule. We have a good many in Chester, but not a street full of gables. The streets in some old German towns show what we have lost. No form of roof can give such an endless play of light and shade, such variety of outline, and yet preserve the identity of every building. The market place at Munster contains a large sprinkling of sixteenth and seventeenth century gables, but chiefly where expense is not the first consideration. The excellence of large Welsh slates as a covering for roofs of 30 deg. tends to maintain to-day the fashions of eighty years ago. On the other hand, in the thousands of little villas—single and semi-detached—which, like mushrooms, spring up in the suburbs, gables, hosts of little gables, can be seen, but hardly ever a large one. A large gable requires to be carefully designed; the small ones only can follow the stock pattern.

I find that Mr. Statham, in his book on modern architecture, comes to the exact opposite conclusion with regard to a street full of gables. He declares that our modern examples are only designed by architects who make a fetish of their skyline; he warns us that there is a risk in the long gutters between adjoining buildings, and adds that the attics under longitudinal ridges are much more uncomfortable than those under cross gables. He ends by recommending flat roofs on town buildings and obtaining a skyline by building some blocks higher than others. A skyline composed of square lumps can look extremely well. I do not think that anyone would deny that who has sailed up New York harbour and seen from three miles or so—not less—the grouping of the sky-scrapers; but to see a row of square lumps every time you look along the street is quite another matter, and surely it is just as difficult to construct a flat roof as a gutter, and the flat roof is more costly, at any rate in the City of Liverpool, where the Health Committee have decided that such a roof is an outside wall within the meaning of the Act, and must therefore be constructed of brick, stone, or other incombustible material.

The superstition that uniformity is the perfection of architecture still lingers to spoil many a skyline. The fallacy is manifest. A building canonly appear uniform from one particular point of view; if that point is the only one, or if the great majority of people can be induced to view it from there, then uniformity becomes ideal. Vanbrugh carried the principle to its logical conclusion in the great carriage-drives which lead up to his country houses. Some of our public buildings, and many abroad, have a large place in front and converging streets beyond it. Under such conditions uniformity can be seen to proper advantage. But on a site with a greater width than the open space in front, or on one approached sideways or diagonally by a principal thoroughfare, uniformity often leads to disaster. One half of the building blocks the view of the other half, the balance of parts is lost or distorted, and features become prominent (such as the roof behind the pediment) to which little or no attention has been given. If more thought were given to large

buildings they could be designed to look their best from the points from which they are most often seen. The tower at the Brussels Law Courts, although by itself most majestic and monumental, appears foreshortened and narrow from the square opposite the main entrance, and cannot be properly seen from any point within a mile. It looks its best from the rising ground two or three miles beyond the lower tower. Considering these circumstances we may fairly ask, was the tower worth the great cost?

Let me close with a sentence from Mr. Ingress Bell: "In a building the skyline is the most important line, for the relief of solid against solid cannot be so sharply defined as the relief of solid against vacancy, and play of light and shade, which we can give to our facades, is as nothing to the contrast of their dark margins with clear air above."

MUNICIPAL IMPROVEMENTS.

The Toronto Guild of Civic Art recently extended an invitation to the different organizations in Toronto which are more or less interested in the subject, to attend a meeting to consider several propositions looking to the general improvement of the city by means of parks, squares, well designed buildings, etc. The meeting was held on the evening of the 21st inst., in the Board of Trade Building, and was attended by representatives from the Ontario Society of Artists; The Ontario Association of Architects; The Canadian Institute; The Toronto Architectural Eighteen Club; The Public School Art League; The Engineers' Club; The Toronto Board of Trade; The Bankers' Association (Toronto Branch): The Canadian Manufacturers' Association (Toronto Branch); The Civic Victorian Memorial Committee.

The following propositions were discussed:—

(1) The appropriate decoration of part of the city on the occasion of the visit of H.R.H. the Duke of Cornwall and York. (2) The purchase by the city of some central park squares. (3) The general improvement of the city by Drives, Parks, Boulevards, etc., and (4) To make representations to the Provincial Government, as to the design and character of the proposed new University Buildings.

The result of the meeting is embodied in the following resolution which was adopted unanimously:—

Moved by B. E. Walker, seconded by Prof. Mavor, "That a Committee be appointed to urge on the City Council the wisdom of conferring with the Guild of Civic Art as to a plan for the general improvement of the City by parks, central squares, drives, boulevards, and other means, such plan to be adopted for the future guidance of the Board of Public Works, and that the Committee shall consist of the delegates appointed by the different organizations to this meeting with power to add to their number."

LEGAL.

The Court of Appeals of the United States has recently put on record the opinion that "an owner who employs a competent architect to prepare plans for a building and lets the work of construction to a competent independent contractor, is not liable for injury to an employee upon the work from the falling of the building while in process of construction, caused by a foreman's negligence in departing from the plans."

A combination of the leading stained glass manufacturers of the United States, is proposed to be capitalised at $5,000,000 the object being to bring the stained-glass manufacturers under a single management, eliminate competition in selling, and reduce the cost of manufacture.

SUGGESTED COMPETITION FOR SCHOOL OF SCIENCE.

The committee of the Ontario Association of Architects appointed to consult with the Minister of Education with reference to the proposed new Science Building in Toronto, had an interview with the Minister and also at his suggestion with the Commissioner of Public Works. Both gentlemen very courteously received the committee. The suggestion offered was the procedure which has been frequently followed both in Great Britain and the United States. When a public building of considerable size and importance is to be erected it is generally conceded that an effort should be made to obtain a design worthy of the occasion. Some method of competition, in fairness to all, seems necessary.

The committee suggested that, in order to secure designs by at least some architects of established ability and reputation, a limited number of such architects be invited to compete, each of whom should receive a certain suitable fee. The selection of these, say four or six in number, might be made equally by the government and the O.A.A. In addition to these appointed competitors, the competition to be thrown open to the profession in Canada. The designs to be judged by a board of say three assessors, composed of Principal Galbraith, the Provincial Architect and a third who might be nominated by the Ontario Association of Architects. This board to draw up the terms of the competition and the general requirements of the scheme.

The committee referred to several important competitions conducted on lines similar to those above outlined with excellent results, and hoped that the department would see their way to adopt some such method of procedure in the present case.

THE COLONIAL BUILDING AT PARIS.

An interesting discussion took place recently in the Dominion Parliament in connection with an item of $90,000 which Canada is called upon to pay towards the cost of the Colonial building at the Paris Exhibition. It was agreed on all sides that the cost of the building was entirely out of proportion to its character. The Minister of Public Works stated that it had to be strengthened, the roof made tight, and the exterior decorated to give it a presentable appearance. The government, while admitting that we had been "taken in," explained that the building was erected entirely under the direction of the Imperial authorities and that if Canada had not accepted the proposal made for space in the building she would have been debarred from taking part in the Exhibition.

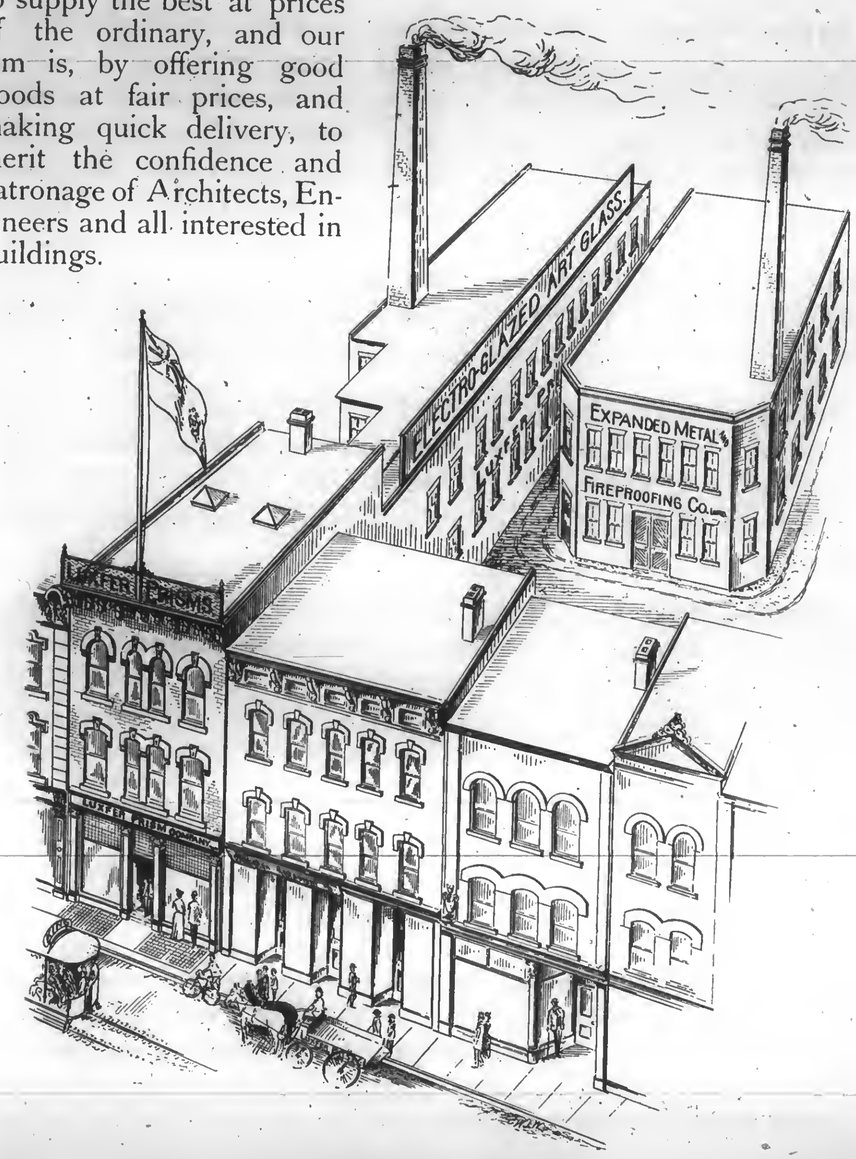
CANADIAN SOCIETY OF CIVIL ENGINEERS.

The Canadian Society of Civil Engineers have arranged to have an excursion to Buffalo in June. The proposal is that the members who may attend will spend a week in seeing the objects of interest in the city and at the Exhibition. The name of Mr. Collingwood Schrieber, Deputy Minister of Railways and Canals, Ottawa, is mentioned in connection with the Presidency of the society next year.

The committee appointed to obtain designs for a statue to Governor Simcoe have chosen the one submitted by Mr. Walter S. Allwood, of Toronto. The statue will be cast in bronze and will be erected under the supervision of the Toronto Guild of Civic Art, in front of the Legislative Buildings, in Queen's Park.

LUXFER SUPPLEMENT.

In all lines we are able to supply the best at prices of the ordinary, and our aim is, by offering good goods at fair prices, and making quick delivery, to merit the confidence and patronage of Architects, Engineers and all interested in buildings.



HEAD OFFICE AND WORKS:

LUXFER PRISM COMPANY, LIMITED,

98-100 KING STREET WEST,

TORONTO.

LUXFER SUPPLEMENT

Luxfer Prisms.—The fact that any part of a building from basement to attic can be lighted by means of Luxfer Prisms is now well established. A tribute to the great success of the Luxfer device for lighting by daylight is evidenced by the efforts made to imitate. One by one these imitations have appeared on the market, with high sounding names, and by cutting prices hoped to obtain business. The first difficulty found by the imitator was in getting a product as effective as Luxfer—the next difficulty the imitator found was that when he cut the price he did business at a loss. Even those now trying to sell ribbed plate as prisms are finding that their scheme does not succeed.

Prices.—In considering Luxfer Prisms it is only fair to compare the cost with a lighting plant and not with ordinary glass. Better manufacturing facilities and the result of experience has made it possible to instal Prisms with more satisfaction and at less cost than formerly.

Electro-Glazed Art Glass.—We have developed a new system of glazing which has proved a great success—the electrically deposited copper bar is neat and strong and where the heavy bar effect is not wanted, it surpasses any other system of glazing and is cheaper than other metallic bars.

Lead-glazed Art Glass.—We also carry on lead glazing for church and domestic art glass work—good taste in selecting glasses and good mechanical work in glazing must result in a more satisfactory product. This has been attained without any increase of cost.

Staple and Ornamental Glasses.—We carry full lines of stock glass, including plate glass, sheet glass, skylight glass, wire glass and fancy colored glasses. Quick delivery at close prices is guaranteed.

Send for prices and particulars.

Luxfer Prism Company, Limited

98-100 KING STREET WEST,

Toronto

LUXFER SUPPLEMENT

Architectural Terra Cotta —As a building material, Terra Cotta dates back to the early centuries, but it is only in modern times that color effects, artistic modelling and the other elements have been commercialized and developed so as to give Terra Cotta the prominent position it now holds as a staple building material. Where ornate work is required, the cost of stone is practically prohibitive, whereas Terra Cotta is as permanent as stone and in both appearance and utility it is the equal of stone. Terra Cotta has the one most important advantage, it is infinitely cheaper than stone.

Samples of the best Terra Cotta products on exhibition.

Pressed Brick.—Like Terra Cotta, the manufacture of Brick comes down from the Ancients. It is, however, only recently that perfect machinery, scientific knowledge of clays and burning has made it possible to produce the perfect article now on the market. The essential for a first-class Pressed Brick is primarily—the right quality of clay. This, with up-to-date plant and skilled workmen, will produce the highest standard of Brick.

Samples of these on exhibition at prices of ordinary brick.

Ornamental Iron.—Artistic work in metal is coming more and more in demand for modern commercial and public buildings. In all kinds of ornamental iron for stair work, railings, etc., we show very fine specimens. Machinery and brains have reduced the cost of producing really artistic work so that it can be introduced in all classes of buildings.

Samples of different classes of metal work on exhibition.

Mica Boiler Covering.—The science of economizing heat has led to the scientific investigation of different classes of materials to ascertain which is the most perfect nonconductor of heat or cold. Probably the most thorough test to which materials are put are those employed by the British Admiralty. Mica Pipe and Boiler Covering has been thoroughly tested, and as an evidence of it having proved superior to all other materials, the British Admiralty have adopted Mica covering as its standard covering. In commercial buildings Mica Covering has proved a success, both on heating plants and refrigerating plants. For brine pipes no other material has been found to stand, and in every way Mica has proved to be the very best insulating material in the market, and is the only covering that can be guaranteed to remain dry and sound on refrigerating pipes.

SAMPLES ON EXHIBITION.

Marble Mosaics.—For a permanent, clean and in every way satisfactory floor, nothing can equal Marble Mosaic when properly put down. All porcelain tile devices have their defects—the chief being the difficulty of getting sufficient adhesion between the tile and cement. Marble Mosaic in its different standard forms, viz :—Roman Mosaic, Irregular Roman Mosaic, and Terrazzo, are, each in its place, a perfect floor. On a proper concrete bed, reinforced with Expanded Metal, and when put down by skilled labor, a Mosaic floor will positively not crack.

SAMPLES ON EXHIBITION.

LUXFER SUPPLEMENT

Expanded Metal.—It is safe to say that no material has met with such general approval as Expanded Metal. It comes on the market just at the time when concrete is claiming recognition in every branch of structural work. A concrete slab is very strong in compression, but lacks tensile strength. Expanded Metal cures this defect, and concrete reinforced with Expanded Metal is destined to be a standard material in all building and engineering works. An eminent scientist has said: **"The twentieth century will be known as the concrete age, just as the nineteenth century is known as the steel age."**

Fireproof Construction.—Expanded Metal and Cinder Concrete makes a fireproof floor, having in it four most important points of excellence, viz.: minimum dead load, maximum strength, minimum cost, and maximum fire resistance. Because of the economy in the construction of Expanded Metal and concrete floors, from the fact that the dead weight of floor is less than any other construction, it can readily be seen that there is a saving in the cost of a building in foundations, steel work and walls. The saving in insurance will soon pay for the extra cost of fireproofing.

No Longer Experimental.—Expanded Metal fireproof construction has been used for several years in the United States, England, Germany, France and other countries. In Canada it has been on the market about two years, and in that short time, so patent are its advantages, the following leading buildings have been fireproofed with Expanded Metal and cinder concrete: La Presse Building, Greenshields' Dry Goods Warehouse, Birk & Son, Jewellery Factory, Guaranteed Milk Co. Dairy Works, Redpath Library, C. P. R. Telegraph Building, Dominion Oilcloth Co. Factory, Dominion Transport Co. Stables, and several others in Montreal. National Trust Co. Building, Sunlight Soap Co. Factory, City Dairy Co. Factory, T. Eaton Co. Warehouse, and others in Toronto. Wood's Dry Goods Warehouse, Conroy Power House, E. B. Eddy Co. Paper Mills, Ottawa Dairy Company, Bronson Co. Buildings, and others in Ottawa. Clarified Milk Co. Factory, Kingston, Sanitary Dairy Co. Factory, London, Lake Superior Power Co.'s Office Building, Sault Ste. Marie, Ont., and several other buildings throughout the country.

Expanded Metal Lath—Since the introduction of Expanded Metal Lath on this market, it has met with the unqualified approval of architects and plasterers This is proved by the fact that although less than three years on the market, there is more Expanded Metal Lath used than all other metal lath put together. The excellence of the key, the facility with which the lath is put up, and the facility with which the plaster is put on, all combine to make Expanded Metal Lath the best metal lath on the market.

The following may be mentioned amongst the many buildings in which Expanded Metal Lath has been used:

Government Buildings

Militia Stores Building, Ottawa.
Custom House and Post Office, New Westminster.
Custom House, Hull.
Custom House, Picton.
Custom House, Brockville.
Armory and Drill Hall, Sarnia.
Armory, Kingston.
Armory, Woodstock.

Commercial Buildings

Canadian Pacific Telegraph Building, Montreal.
La Presse Building, Montreal.
National Trust Building, Toronto.
Sunlight Soap Co.'s Offices, Toronto.
E. B. Eddy Mfg. Co.'s Buildings, Ottawa.
Capital Power Co.'s Building, Ottawa.
Lake Superior Power Co.'s Offices, Sault Ste. Marie.
Dominion Iron & Steel Co.'s Building, Sydney.

PRICES AND PARTICULARS ON APPLICATION.

LUXFER SUPPLEMENT

The Latest Improvement in Plaster Work.

Pulp Plaster.—There have been many Patent Plasters put on the market of late years—all having some merit—but none have met the full requirements until the production of Elastic Pulp Plaster.

In Elastic Pulp Plaster, a distinct innovation is established. Sand and lime are completely abandoned and a compound is produced composed largely of wood pulp, combined with cements and other plastic materials, which has many advantages over the common sand and lime plaster.

In its production, the plastic art is brought abreast of the advances in other departments of the building trade, and we feel confident that this will be appreciated by the public generally and that Elastic Pulp Plaster will soon become known as superior to all the other plasters in use.

ARCHITECTS specify it

Because it is quick-drying, light in weight, and will not crack or crumble.

Because it has no lime or acid to destroy the color in paper, paint or kalsomine.

Because it is waterproof and fireproof and a deadener of sound.

CONTRACTORS use it

Because it works cool, spreads freely and can be trowelled smooth for papering or coloring in ONE COAT.

Because it adheres equally well to brick, stone, metal or wood lath.

Because it is tough and elastic, and needs only very small key to hold to the lath.

Because it can be used in cold weather without damage by frost in green state.

Because they can save HALF THE COST OF LABOR, as compared with ordinary plastering.

Because it will cover 140 to 160 yards per ton.

OWNERS want it

Because it makes a dense, hard wall, that will not crack, crumble or discolor.

Because it is a perfect insulator and prevents escape of heat through the walls, saving one-third of the fuel to heat a building.

Because paper or paint can be applied immediately without damage to colors.

A factory for the manufacture of Pulp Plaster has been established in Toronto with a first class equipment of machinery and appliances for compounding.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO., of Toronto, Limited.
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.
Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the followowing terms: Architect's Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated hy the subscriber; but where no such understaodiog exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not latter than the 12th, and changes of advertisements not latter than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

LEGAL.

J. and C. Low, contractors and builders, of Ottawa, were defendants in an interesting action, in which judgment has been given. Defendants had the contract to build a summer cottage on Rabbit Island in the St. Lawrence last summer. They sub-let the contract for plumbing to King & Burnette, of Lansdowne, for $500. The cottage was destroyed by fire when almost completed. The sub-contractor sued the contractors for $488, claiming that amount of work was done when the cottage was destroyed. They were allowed this amount by the Jury at the Brockville Assizes. Chancellor Boyd reserved judgment on a legal point raised by defendants' counsel. He however, gave judgment in favor of plaintiff.

WHERE DOES A BUILDING BEGIN?—An exceedingly novel point under the Workmen's Compensation Act was raised before Judge Parry at Manchester County Court. Christopher M'Grath, while bricksetting on a warehouse that was being erected by Messrs. Neill and Sons, was thrown from the second story to the basement by a plank suddenly tilting up. He therefore claimed damages for injuries sustained. The question at issue was one as to whether the height of the building should be calculated from the street level or from the level of the cellar. It was argued that if the street level were to be taken the 30 feet required by the Act would not be obtained, and the action could not succeed. Judge Parry expressed his opinion that the only way of measuring was to begin at the bottom of the brick, inasmuch as a builder began at the bottom, whether it was above or below the street level. As the point, however, was a very important one, he would reserve his decision.

Canadian Industries and Canadian Products are taking the lead the world over. Why should not Canadian Varnish do so at home? When making out the specifications for your next building, remember that

The Imperial Varnish & Color Co.'s Limited

HIGHEST-GRADE ARCHITECTURAL VARNISHES

are designed for first class work, and are not surpassed by any of a foreign make. Try them. Put up in tins with our brass seals. :: :: :: :: ::

MANITOBA CORRESPONDENCE.

(Continued from page 104.)

to each set of rooms leading from the main entrance hall, so that when the hall door is closed the suite is quite shut off from the rest of the building. The question of good ventilation and plenty of sunlight are matters which the designers of such buildings should well consider. Disease may lurk more in structures of this kind than in private houses il the question of sanitation, light and air is not well considered and provided for in the construction.

An attempt was made some time ago to form an architectural association here but for one cause or another it fell through. An association of this kind is much needed and might be made very useful. We can all learn very much from one another and a general rubbing up of ideas at monthly or other meetings would do any of us good and add much to our usefulness. One thing we might consider is that there should be some standard by which any one desiring to practice as an architect could or should be measured.

Some contractors are in the habit of drawing sketches or getting plans and then offering to put up the buildings. This is a bad practice, and as a rule it leads to a poor class of buildings (architecturally speaking) being erected, and is a loss to the legitimate architect who would be commissioned in most cases to prepare the plans and superintend the work. We have known cases where buildings designed by an architect have been almost duplicated in the way referred to. Imitation may be the sincerest form of flattery, but it is not a paying thing for the architect, nor is it fair or right.

It seems a very difficult matter to get the architectural profession placed on a proper basis. The members of other professions such as Lawyers, Doctors, Dentists, etc., are allowed to protect themselves and the public, while architects get no protection or legalized standing. Combines seem the order of the day but an architectural combine seems to be out of the question up here, for the present at any rate.

The Parks Board have taken charge of the City Hall square and are planting extra trees and intend to lay out flower beds. This is a move in the right direction. They have also charge of all boulevarding in the city and will plant trees on a definite plan, charging the cost up to the owners. This will beautify and improve our streets, as trees add much to the appearance of street architecture.

NOTES.

The foundation for J. G. Hargrave & Co's store on Main st. is well under way.

Progress is being made with the foundation of the new Merchants' Bank building and some good work is being done.

CATALOGUE FOR THE ASKING

BUILDING IN CHICAGO.

The Chicago Building Contractors' Council, which recently cast off the yoke of the Building Trades Council, celebrated the victory by holding a banquet. Since the deadlock in the building trades in Chicago was broken, building activity has been so great that supply firms are finding it difficult to meet the demand for certain kinds of materials.

A dispatch from London states that a few weeks ago a small marble shaft fell from one of the windows in St. Andrew's Chapel, in Westminster Abbey, the iron pin that had sustained it for 600 years having become corroded. Iron pins are doing the same duty in innumerable places throughout the Abbey and further dilapidation is apprehended. To overhaul and renew these pins would be a superhuman labor. Professor Church says that the use of gas as an illuminant in the Abbey, which is a limestone building, sets up a chemical change which is followed by disintegration. It has been suggested as a means of checking further decay that the Abbey be lighted by electricity, as is St Peter's at Rome.

Gold leaf may be tested for purity by putting a few drops of nitric acid upon a glass, and then placing thereon a small piece of the leaf. Pure gold leaf will not be affected by the acid.

Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.

Sold to the Trade Only. *Sole Licensees for the Dominion of Canada* *Send for Discounts.*

PERSONAL.

The sons of the late Thos. Haskins, who was for many years city engineer of Hamilton, have recently had erected a memorial window in St. Thomas Church.

Mr. Thos. C. Sorby, architect, of Vancouver, B.C., is writing a series of articles on "Domestic Architecture in England During the Middle Ages," for the American Architect.

Mr. W. H. Law, late chief engineer of the Hamilton Bridge Company, has been placed in charge of the structural iron department of the Canada Foundry Company, Toronto.

Mr. J. O. Marchand, of Montreal, who has just completed a course of study in architecture at the Ecole des Beaux Arts, Paris, has distinguished himself by winning a competition in design over the heads of 400 rivals of all nationalities. He has been awarded a first-class medal, and his work has been purchased for the library of the school.

Mr. Henry B. Gordon, of the firm of Gordon & Helliwell, architects, of Toronto, has gone to Corea, having received a commission from the King, to supervise the erection of a new palace, hospital and other important buildings. He expects to be absent at least a year. Previous to his departure his many friends tendered him a complimentary banquet at McConkey's and presented him with an illuminated address.

Mr. G. F. Todd, landscape architect, of Montreal, spent a few days in Toronto recently, and was a guest at the weekly luncheon of the Ontario Association of Architects. He had also an interview with the Mayor regarding the improvement of the Industrial Exhibition grounds on the lines suggested by the O. A. A., and the laying out of central squares, and such like methods of improving the appearance of the city.

An English paper states that Mr. Edwin O. Sachs, the architect under whose direction a series of valuable tests of fire proofing materials is being conducted in London, is not yet thirty years of age, but has already started four times at the lowest rung of the ladder—not as a necessity, but as a means of instruction. As an architect, he started by working as a bricklayer for four months. As an engineer, he worked in the smithy. To understand stage construction he became sceneshifter at half-a-crown a night for four hours' labour; and, lastly, to learn everything connected with fire and its prevention, Mr. Sachs joined a fire brigade for six months in Vienna, afterwards serving in Berlin.

SASH CORD.

Too little attention is paid to the small item of Sash Cord. A poor quality rough cord wears out in a very short time, and requires the services of a carpenter, while a good smooth solid braided cotton cord wears for many years.

In order that users of sash cord may always feel sure of getting a first quality cord, having the very best reputation for many years, the Samson Cordage Works adopted some years ago as a trade mark the "Colored Spot," appearing at intervals in the cord. This is used only in their first quality cord, which should be specified as "Samson Spot Cord." The manufacturers will be glad to furnish copies of tests made by the Massachusetts Institute of Technology, and full information together with samples.

Mr. W. F. Tallman, who for some years was engaged with his father, in the manufacture of brick, at Beamsville, Ont., has gone to Edmonton, N.W.T., to assume the management of a brick-making plant about to be put into operation there by Messrs. P. Anderson & Company. It is expected that the plant will commence operations this month. It will be located between Strathcona and Edmonton, on a line of railway now surveyed. The plant will be quite extensive, having a capacity of 50,000 bricks per day, and although there are three other plants in the town, it is anticipated that all the brick manufactured by the different plants will be required for construction in Edmonton and vicinity. No stone is procurable within a distance of one hundred miles, and as a result brick is used for foundation purposes. In the town of Edmonton alone it is estimated that 4,000,000 bricks will be used this year. It is probable that, in addition to common brick, the company will manufacture sewer pipe, sidewalk brick, and if the clay should be found suitable, pressed brick also. In Mr. Tallman, the company have secured a manager whose ability and experience warrants the prediction of successful operations.

LEGAL.

BLAIS VS. THE GURNEY-MASSEY CO.—This case came up before Justices Gill, Mathieu and Loranger of the Court of Review, Montreal, on the 9th inst. The defendant inscribed in review from a judgment which maintained the plaintiff's action and condemned the defendant to pay $400 damages. The case arose out of the purchase by the plaintiff from the defendant, in the fall of 1899, of a steam-heating apparatus, styled in the defendant's catalogue, "Gurney's Bright Idea Water Tube Steam Boiler." The plaintiff had entered into a contract with the Fabrique of the parish of Ste. Martine, district of Beauharnois, for the installment of a heating apparatus, to heat the parish church. The defendant published a catalogue in 1897 in which the particular apparatus purchased by the plaintiff was represented as having a heating capacity of 2,400 square feet of radiating surface, equivalent, as appeared by the evidence of experts, to 7,200 linear feet of one-inch pipe, the price of which was $686. In 1899 the defendant published another catalogue, in which it appeared that the heating capacity of this apparatus was reduced to 1,800 square feet, equivalent to 5,400 linear feet, and the price was reduced to $600. After the apparatus was installed it was found that it would not heat the pipes and the rest of the system with which it was connected. The plaintiff protested the company defendant, and called upon it to replace the apparatus with one of a capacity of 7,200 linear feet, as stated in the catalogue of 1896. The defendant refused to do this, alleging that it sold the apparatus according to the catalogue of 1899, wherein the capacity was guaranteed to be only 1800 square feet; that the apparatus had that capacity, and if it did not heat the pipes of the church sufficiently, it was owing to their too grea extent. The court below decided in favor of plaintiff's pretension as to the catalogue, but rejected his claim for damages to reputation, and reduced his demand of $647, for replacing the heating apparatus, to $400, and this award appearing to the Court of Review to be well founded, the judgment was confirmed.

A prominent insurance adjuster makes the statement, that a large majority of the recent fires in the city of New York have resulted from imperfectly insulated electric wires. He says that this is due to the fact that the contractors for electric wiring employ boys and inexperienced men to do the work, rather than be obliged to pay for the services ot experienced electricians, and that the vibration and settlement of walls frequently destroy the insulation where proper preventives have not been employed. He adds: "It, therefore, behooves architects to specify that none but thoroughly competent and experienced workmen shall be employed, and they must not trust entirely to the electrical contractor, but examine the work themselves with the same exacting care that they devote to work done by other builders."

LETTER FROM THE TORONTO ARCHITECTURAL EIGHTEEN CLUB.

Publishers CANADIAN ARCHITECT AND BUILDER:

DEAR SIRS:—We received your communication of the 8th ult., informing us that a certain local architect and some others have strongly objected to one illustration page of your journal being reserved for our Club, with that fact printed on said reserved page, as has been the case for some months past; and further that if such "distinction thus given to us be not removed, they will in future decline to give" you "drawings and photographs of their work for reproduction."

We beg to say that our idea in introducing this innovation was that our Club would be enabled thereby to exercise strict censorship over the published work of its members, and, at the same time endeavor to create a friendly rivalry in the quality of their published work and that published by the rest of the architectural profession of Canada—a result we considered beneficial, at once to our country, your journal and the profession at large.

That through your enterprise we have succeeded by means of our reserved page in bringing an increased measure of favorable notice to the work published on your illustration pages is amply proven by turning to the critical pages of the Architectural Review published in Boston, from the pen of one of the foremost architectural critics on this side of the Atlantic.

We had not the remotest idea, till we received your letter that anyone imagined that our members had secured undue distinction beyond their fellows. Therefore we desire to relieve you, as suggested, "From the unpleasant situation in which" you "find" yourselves "placed through circumstances over which" you "have no control." We would keep no impediment in the way of this gentleman and his friends; we wish them to supply you with their photographs and drawings for reproduction. Therefore we cheerfully accede to their request that we be treated as other architects contributing to the illustration pages of your journal. But we think we will not avail ourselves of their liberal offer, viz., that when, in future, any of our members may, individually, as all architects contributing to your pages, send you drawings for reproduction, they shall have the privilege of announcing on the page that they are members of the Eighteen Club.

But some matters must not be taken too seriously. Some of us remember how in our student days amusing stories were told us how the "old fellows" of the then "old days" would allow nothing architectual to be done, no matter how excellent, unless something in the shape of precedent could be hunted up to warrant its adoption. Happily those days of architectural practice have long since gone by, though apparently some vestige of the principle remains in the minds of our esteemed contemporaries as you quote them in your letter as objecting to our reserved page on the ground that "There can be found no precedent" for it "among the architectural journals of other countries."

In conclusion we specially request this letter to be printed in full in your next issue as we think it only fair to our Club that your readers should know the reason of the non appearance of our former reserved illustration page.

Yours truly,
J. P. HYNES,
Sec. pro. tem.

TO INTENSIFY BLUE PRINTS.

In a recent issue of the Photographisches Wochenblatt is an article advocating the use of peroxide of hydrogen for giving greater intensity of color to blue prints. It will be remembered that a blue print is not as intense on leaving the washing water as it is after some 24 hours' exposure to air, an effect assigned to oxidation. To remedy this, it is suggested that a few drops of peroxide of hydrogen be added to the water, to increase the rate of oxidation. The scheme is also useful when the paper is old and gives veiled prints. In case the sensitized paper has turned a greenish blue, it should be over printed until a decided image is visible. Then a little washing soda solution should be added to the washing water, but it should be used sparingly. The washing should be repeated until the whites are clear, and then the prints should be given a final wash in water to which a small quantity of peroxide of hydrogen has been added.

FIRE-PROOF GLASS WINDOWS
THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

The Evil of Strikes.

As the result of a lengthened strike of Belgian glass workers, for a greater increase of wages than the manufacturers could afford to pay, the trade of these manufacturers has gone to other countries, a once prosperous industry has been lost to Belgium, and ruin has come to those whose means were invested in it. The competition engendered by the emigration of large numbers of the strikers to the United States, is said to threaten the life of the window glass trust in that country.

The Proposed Art Gallery in Toronto.

It was announced not long ago that $30,000 for this building was in sight, leaving only $20,000 to raise to make half the cost of the building; and it was contended that, when the half was raised by voluntary contribution, the city ought to supply the rest. This is a reasonable proposition, and it suggests the possibility of the whole scheme being put through in time for the Duke of Cornwall and York to lay the corner stone. The city's subscription, once agreed upon, is but the stroke of a pen. It is only the $20,000 of voluntary subscription that need take any time, and it need not take much time. It is not hard to find in the city of Toronto one man who is able to give $20,000, nor two who can give $10,000, nor four who can give $5,000, nor even twenty who can give $1,000. There is hope for the accomplishment of such a purpose as getting the memorial to Queen Victoria advanced far enough for her grandson, and our future King, to lay the corner stone. The fashion of giving has not been in vogue among the original rich of Toronto. Perhaps it was not so much their fault as the fault of their times. Rich men had not discovered what is now being discovered, that one of the blessings of wealth is the power to give. Can there be a greater enjoyment of wealth than the power to say that there shall be an Art Museum in Toronto? Several gentlemen have already decided to say this, with an emphasis proportioned to their means; and if the committee, who have the project in hand want to get a sub-committee who will put the matter forcibly before other gentlemen of means, we would suggest that they ask the present subscribers to form such a sub-committee. They have a right to ask others to subscribe; and will be able to persuade others to taste what, if one may judge from recent examples, is the latest enjoyment of rich men—the pleasure of giving.

Re Beautifying Toronto.

The Toronto Guild of Civic Art has been trying to move the civic authorities in the direction of an improved plan of the city, towards which all extensions and improvements may work; so that every piece of work undertaken in the way of laying out new streets in the suburbs, or opening up new streets in the old part of the city, may tend towards the accomplishment of a definite scheme which will make Toronto a fine city.

It was well contended by the deputation from the Guild that this was a matter beyond the scope of volunteer advice such as the Association of Architects have offered in the minor matters of rearranging the fair grounds or preserving an ornamental water front in the centre of the city. The Mayor's reply that, if a plan which would cost money was necessary, the Guild of Civic Art ought to collect half the sum necessary for it, was probably the most practical politics, though, abstractly, the work is eminently a public work, and is only an expense in the first instance; for it would undoubtedly in the end save many times its cost.

Economy was the word with the Board of Control. Let us then point out a civic improvement that would be a saving; which at least would have been a saving if nothing had yet been done, but now involves the slight expense of some uprooting, for it is the uprooting of what has been planted that constitutes the improvement we would suggest. Somebody has conceived the idea of spotting the Queen's Park over with little conical evergreens. Whether these remain dwarfs or grow to any considerable size, the Park is in either case spoiled; and it is difficult to understand how any official, of sufficient attainments to be in a position of authority in this department of the city, could not see how totally at variance these plantings are with the character of Queen's Park. The history of the Queen's Park is probably that of most of the parks which are adjacent to the country seat of an English landed family. It was originally set apart for pasture land, and trees have been allowed to grow up sufficient for shade without being so close as to spoil the grass. The resulting character of sweeping lines of grass, harmonizing with the spreading growth of trees which stand alone or in groups, constitutes to English people the idea of a park; and that sort of park we had in greater perfection than many an English nobleman, until this bush planter came along and intercepted every vista under the trees by his little stiff cones of fir, so that the eye can no longer follow the long sweeps of surface which were the characteristic beauty of the park.

Doubtless the idea comes from the new American parks, in which a garden style is adopted as the only thing available until trees can be grown. To imitate this at all is only excusable under the same conditions, and one may expect from the committee of parks and gardens not only a perception that the two styles cannot be mixed, but a perception that the style of the Queen's Park is much the finer. It is only an understanding of the ground of beauty in the Queen's Park that can preserve it not only from this danger but from a danger which continually threatens, of tampering with the ravines so as to spoil the slopes which are so essential to the beauty of the park. Trees on a slope have always made a favorite theme for painters, and, whatever happens to the bottom of the ravines, it ought to be well understood that the grassy slopes must be preserved.

The New S.P.S. Building.

The Guild of Civic Art is also taking a hand in the effort to have the new School of Practical Science Building made worthy of the city. It is supported by representatives from most of the important public bodies in Toronto, who have united with the Guild to form a special committee for this purpose. An interview with the Premier has been arranged, but so late in the month that it is probable the Premier's answer will be— with much regret— that it is too late to do anything. It is understood that the Provincial Architect's office is already engaged upon plans of the building. It is now or never that the case of this building must be pressed. The Premier and the Minister of Education have both spoken in such a way as to lead to the belief that they wish to have this building well designed, and are disposed to regard favourably a liberal policy in regard to the appointment of an architect. That liberal policy which will be most effectual is to be found in practice in the United States, where private architects of repute are employed for the erection of public buildings. The Minister of Public Works, who seems to think his department is being "passed over" unless the provincial architect is not only the supervisor but the designer of the new building, will find, if he enquires about the present method in the United States, that there is no occasion for such a feeling. The Federal architect and the State architects still exist and have plenty to do, but, though it is such a short time ago since the struggle arose with these departments—the same struggle as is taking place over the School of Practical Science Building— to have important buildings put in the hands of architects in private practice, the question is completely settled, settled on its merits. Public opinion and official opinion are at one in the matter. Indeed, so settled has the idea become that this is the only way to procure good public buildings, that the government is now quite as anxious as architects or the public not to lapse into the old way of doing things. Some misunderstandings have arisen, the American Architect says, in applying the bill under which treasury work is given out to competition of invited architects, and some of the most eminent architects in the country have declined invitations to compete for government work. In consequence of this, the Secretary of the Treasury has been conferring with the President of the American Institute of Architects, in order to remove the conditions which have led to misunderstanding. It is evident that the Secretary of the Treasury agrees with the American Architect that "the refusal of the best architects to enter into government competitions would be a public misfortune." This is after experience of the working of this method, which had when first proposed to encounter the identical opposition which, if we may judge from his words, it is encountering now in the mind of the Hon. Minister of Public Works in Ontario. It is for this reason that we recommend to him to make enquiries about the American method of proceeding, and we think he will find that he will pursue a course most to the credit of his department if he requests the public architect to utilize the study he has so far made of the subject, and the special information he will acquire on his trip with Professor Galbraith, to draw up a full statement of the requirements and conditions of a properly arranged building for the school, and to act afterwards as one of the expert arbitrators to judge the results of either a limited competition or an open competition.

We are reminded by this Ontario situation, of a motion that was made in the convention of the Ontario Association of Architects, to memorialize the Dominion Government upon this same subject of appointing private architects to design public buildings, or giving the buildings out to competition. The question was referred to the council to act upon as they should see fit. The council appear to have seen fit not to act upon it, but it is a question whether this was what the convention intended.

New German Schedule of Fees

A new schedule of fees has been adopted in Germany, which affords interesting study. In the first place, it is adopted not only by the architectural societies, but by engineers, constructive, heating, gas, water, electrical and mechanical, who appear to be united in one association with the architects. Fees are determined upon principles common to all the associated professions. Specialties have special sections. The liberality of the principles upon which fees are computed is worth studying. In the matter of preliminary studies, a large view is taken of the importance of this part of the work, and more intelligent provision is made for proper payment than a hard and fast rule of 1 per cent. Where a commission embraces several structures of the same design, to be executed simultaneously, the fee is reckoned for supervision upon the whole cost, which is natural, and for other services according to the work done, which is also fair; but preliminary studies too get consideration on the basis of total cost. When a commission consists solely of the preliminary sketches, the fee is to be increased one-half. Where preliminary sketches, agreeing with different programmes, are desired, each is considered independently. In case of several preliminary sketches being desired for the same site and programme, the full fee is estimated for the first, and compensation for the others is based on the additional work they require. In case there are no preliminary sketches, but the architect is called in at the stage of working drawings, (a strange case), the fees for working drawings and specifications are increased one-fourth. On behalf of the client, there are special provisions that all commissions or rebates will be turned over to him and that he may ask for expedition in the preparation of plans without incurring an extra charge. The client is to bear the cost of all contingent work, that is to say, of all surveys, measurements, examinations of foundations, etc. He is to pay the salaries of inspectors and superintendents, the expense of establishing and running a special office, the cost of advertising and closing contracts, and that of measurements for the final estimates. The cost of engineering advice to an architect, or of architectural advice to an engineer, is also borne by the client. Work by time is $5 for the first hour, and $1 for each hour additional. For journeys $6 a day is added to the usual fees; but this charge can be made only once, i.e., if two or more clients are served by one journey, the $6 charge is divided according to the facts of the service.

With such handsome allowances for services beyond ordinary necessities, one would expect to find the ordinary charge kept rather slim, but it is not so. The method of computing the fee is by percentages upon a sliding scale of cost and under four heads of elaboration in the character of the work; so that the fee increases as the proportion of finish in the work increases and decreases with the increase of total cost. The headings of degree in elaboration are not set forth in terms of the character of the work, but in terms of the percentage of finish. There are four such groups, and a fifth of furniture and fittings. The table will best be explained by reproducing it in extenso:

Architectural Fees, in Percentages of Cost of Construction.
Minimum Charge for Groups I–V

Total Cost in Dollars.	I	II	III	IV	Extra for no e finish.	Charge for Group V.
	Percentage Finish is to Total Cost.					
	20%	30%	40%	50%		
250	6.00	9.00	12.00	15.00	0.135	21.00
500	5.60	8.40	11.20	14.00	0.125	19.60
750	5.30	8.00	10.60	13.30	0.120	18.60
1,000	5.10	7.70	10.20	12.80	0.115	17.90
1,250	4.90	7.40	9.80	12.30	0.110	17.20
1,500	4.80	7.20	8.60	12.00	0.108	16.80

2,250	4.55	6.85	9.10	11.40	0.103	15.95
2,500	4.50	6.80	9.00	11.30	0.102	15.80
3,750	4.30	6.50	8.60	10.80	0.097	15.10
5,000	4.10	6.00	8.20	10.30	0.093	14.50
6,250	4.00	6.00	8.00	10.00	0.090	14.00
7,500	3.90	5.85	7.80	9.70	0.088	13.60
8,750	3.80	5.70	7.60	9.50	0.086	13.30
10,000	3.70	5.55	7.40	9.30	0.084	13.00
12,500	3.50	5.40	7.20	8.00	0.081	12.60
15,000	3.60	5.25	7.00	8.70	0.079	12.20
17,500	3.40	5.10	6.80	8.50	0.077	11.90
20,000	3.35	5.05	6.70	8.40	0.076	11.75
22,500	3.30	5.00	6.60	8.30	0.075	11.60
25,000	3.25	4.95	6.50	8.20	0.074	11.45
37,500	3.10	4.70	6.20	7.80	0.070	10.90
50,000	3.00	4.50	6.00	7.50	0.067	10.50
62,500	2.90	4.30	5.80	7.20	0.065	10.10
75,000	2.80	4.20	5.60	7.00	0.063	9.80
87,500	2.75	4.10	5.50	6.90	0.062	9.65
100,000	2.70	4.00	5.40	6.80	0.061	9.50
125,000	2.65	3.90	5.30	6.60	0.059	9.25
150,000	2.60	3.80	5.20	6.40	0.058	9.00
175,000	2.55	3.75	5.10	6.30	0.057	8.85
200,000	2.50	3.70	5.00	6.20	0.056	8.70
225,000	2.45	3.65	4.90	6.10	0.055	8.55
250,000	2.40	3.60	4.80	6.00	0.054	8.40
312,500	2.30	3.45	4.60	5.80	0.052	8.10
375,000	2.20	3.30	4.45	5.60	0.050	7.80
500,000	2.10	3.20	4.30	5.40	0.049	7.50
625,000	2.05	3.10	4.15	5.20	0.047	7.25
750,000	2.00	3.00	4.00	5.00	0.045	7.00
1,000,000	1.95	2.95	3.90	4.90	0.044	6.85
1,250,000	1.90	2.90	3.80	4.80	0.043	6.70
1,500,000	1.85	2.85	3.70	4.70	0.042	6.55
1,750,000	1.80	2.80	3.65	4.60	0.041	6.40
2,500,000	1.75	2.70	3.55	4.50	0.040	6.30

Note: In using this table, the total c st will be rounded off to the next hi her tabulated amount provided the fees are increased by so doing.

INJURIOUS EFFECTS OF GAS ON ASPHALT.

The fact has been established that the gas escaping from underground mains injuriously affects asphalt pavements on streets where such leakage of gas occurs. The first noticeable effect is checking of the surface of the asphalt. This is followed by general disintegration. Instances are recorded in which asphalt paving contractors have declined to fulfill their agreements to keep roadways so affected in repair, on the ground that their destruction was not due to defects in workmanship or to ordinary wear and tear of traffic.

MASTER PLUMBERS' CONVENTION.

The annual convention of the National Master Plumbers' Association of Canada will be held in the Temple Building, Toronto, on the 26th, 27th and 28th inst. The Executive will meet at 9.30 a.m. and the convention at 2 p. m. on the 26th. A large attendance is looked for, including representatives from the various Provincial Associations. Reports of the work done during the year will be presented and discussed. The local plumbers and plumbing supply firms have appointed a joint committee to arrange for the entertainment of the visitors. On the 27th inst. they will be given a carriage drive around the city, and in the evening will be held the annual Association banquet. After the election of officers and completion of the business on the 28th inst., it is proposed to make an excursion by electric cars to some place of interest outside the city, and there enjoy a musical program and luncheon. Strong inducements are being offered the Association to hold the annual convention next year in Halifax, Nova Scotia.

DECORATION METHODS AND MATERIALS.

By W. H. Elliott.

In attempting a short description of the methods and materials employed in interior house decoration at the present time, I shall endeavor to be as concise in my statements as possible—describing the material, its advantages and disadvantages, where it may or may not be used satisfactorily: and so of the methods employed.

As in other things decoration has its fashions—styles come and go in public favor, and in five years the decorations of a house may be quite out of date. This would be unfortunate if it were necessary. Many styles are never out of date and they are usually the most desirable, temporary styles having their destruction inherent in themselves. It is quite possible to carry out a scheme of decoration which if entirely appropriate to its position will always give lively satisfaction both in color and design.

I might also refer to some notions at times prevalent about the use of color which do duty for the time as decorations. Not long since I heard a lecture in which the theory that each color symbolized an abstract idea was gravely set forth—as that red was love—yellow, aspiration, etc. The folly of attempting to embody such ideas in schemes of decoration would be apparent to any one giving only slight attention to the subject. Of equal value was a scheme for the decoration of a church in which the color of the lower wall represented the bark of trees, higher up the leaves, then a golden sunset, and above all the pale green and blue of the evening sky. Very fanciful no doubt and possibly resulting in good hands in a harmonious arrangement of colour, but on what ground are we to transfer bodily the outer landscape to the walls of a church?

The possible scheme of colour is not objected to, but the gravity with which these and similar fads are presented as principles of decoration. The principles of decoration are worked on other lines. The amount of light usually governs the strength or depth of colour; the presence or absence of sunlight has its due weight, the purposes of the room, the tastes of its customary occupants and a hundred other considerations which are, not fanciful, but very practical, influence the decorator in his work.

To follow some of these theories would be to tie ourselves to a certain arrangement for certain conditions in every case. For example a very cheerful room may be carried out with blue as its motive color (no matter what its signification may be) and a very dismal room may result from a badly balanced scheme in yellow. And here let me say that in most cases one color should strongly predominate when a successful effect is desired. Too positive colors in nearly equal proportions are fatal to repose of any room. The exception to this is of course when the color is thoroughly broken up as in the Moorish or Romanesque styles. Another rule which is very safe is that all three primary colors should be represented in every scheme of decoration, otherwise a tame effect is certain. The red or yellow may be very much subdued in a blue room, and so of the other combinations, but their presence if ever so quietly introduced, is unconsciously felt as a satisfying impression.

Looked at from the standpoint of durability many of the materials employed are far from satisfactory, but happily or unhappily, durability is not often considered in present day decoration. The universal surface material, plaster, is anything but durable. Various attempts have been made to produce substitutes, but thus far without conspicuous success. For small surfaces what has been named plaster board is something of an improvement. It is usually a thickness of plaster-of-paris or ashestos in which coarse canvass or scrim has been incorporated. When this material is cast in ornamental forms such as cornices, friezes, centres, &c., it is called staff. Lightness and strength are obtained by this method and some comparatively large sections have been cast in this way.

For finer ornament various compositions are used which admit of plastic moulding to a limited extent. Ornament of this nature has become necessary on account of the extensive use of the French styles of the Empire, Rococco, etc. As a practical substitute for plaster the sheet metal designs so largely placed on the market at present are very satisfactory where the decorative effect is of little importance. They can hardly be classed as decorative material.

Where any work of importance is contemplated it is advisable to first cover the plaster surface with a strong cotton or burlap, so that cracks may not eventually injure the appearance of the work. Burlaps of various degress of coarseness are now used extensively for covering wall surfaces and are invaluable for the purpose—the texture giving an excellent surface for color or decoration. The color is obtained either by painting the burlap after it is fixed or by using the ready dyed materials which may be obtained in all desirable colors. Burlaps, cottons and other similar materials are applied to the wall with ordinary flour paste, the wall being pasted instead of the material. Joints should be overlapped about an inch to allow for shrinkage, left several hours, then cut through both thicknesses with a sharp knife, the strips removed and the two edges brought neatly together. Dyed material does not require overlapping as it is already shrunk. For painting, a rather open weave is preferable, the color not filling it so as to hide the texture.

Decoration in glaze colors, outline relief work, and other methods are employed with excellent effect on the painted burlap. Silks and woven tapestries are also used to a limited extent for covering the walls of the more important rooms of the house. The cost of these both in material and application is of course much greater than that of other coverings, and it is questionable if the results gained justify the additional cost. These materials are usually tacked to thin strips of wood which have been nailed on all angles of the wall, the joints being concealed by silk cord gimp or rounded strips of wood which have been covered with the wall material. A lining of ordinary cotton or Canton flannel is usually applied first to the wall to protect the more expensive material from dampness and to give a softer surface. Hand-woven tapestries are only possible to the very few, so that practically we are confined to the products of the machine loom. All of these are closely reproduced in the many beautiful wallpapers now to be had. I have always maintained that such imitation is perfectly justifiable, as the material or groundwork is only a medium for transferring the design to the wall and of no importance in itself beyond its suitability for the special work in which it is employed. Ordinary silk will not retain its appearance on the wall as long as its reproduction in wallpaper, its

texture making it a receptacle for dust, smoke, etc., which in a short time completely ruins its surface. No doubt this is more especially true of our houses in Canada, shut up closely as they are during a long winter with the accompanying accumulation of dust.

This brings us to the consideration of wall paper as a medium for decoration—a material more generally used than any other and undoubtedly more broadly adapted to the various requirements of house decoration. As I have already said, wall paper has been designed to reproduce other materials in a cheaper and more practical form. Silk, leather, tapestry, cretonnes, etc., are now to be had in wall paper in their choicest designs. The first cost of die cutting, etc., being distributed over a large output the richest and most elaborate examples of each fabric may be copied. How one is deceived by these reproductions when on the wall, but one may have the very best of design and weave the world affords, while if attempting to use the actuat fabrics only a very moderate and perhaps undesirable selection is possible. There is of course a very large range and very superior range of designs which are not copies of anything but simply wall paper.

Wall papers are broadly divided into hand-made and machine-made—pressed flat, gilt and color. The manufacture of hand made papers follows somewhat the earliest type of printing press, but while the old printing press has long been discarded, the hand or block printing machine still retains a large place in wall paper manufacture. The advaotages are a more solid layer of color and as a consequence a more forcible effect on the wall. Large designs also may be printed with blocks when the expense would be too great to construct a machine for the purpose. But of late years, with perfected machinery and skilful printing many designs are produced which test the ability of an expert to detect as not hand. made. The best designs come from England—that is designs which are purely wall paper, not imitations of any other fabric. Such men as Burne Jones, William Morris, Lewis F. Day, Walter Crane and others have given their best efforts to the designing of wall paper and the result is what might be called a school of wall paper design which is drawn upon by the designers of other countries. These men by no means treat the wall as in all cases merely a background for other things, but rather as an important feature in the furnishing of the room. Of course where important pictures are to be hung many of their designs would be quite inappropriate, but unfortunately the number of important pictures bears a ridiculously small portion to the number of rooms to be decorated. French designs excel in reproduction of silks, leathers, etc. and many of their papers are exquisite examples of the art of wall paper making. By far the largest proportion of designs are studies of natural flowers slightly conventionalised. Always popular and easier of treatment than ornament. they peculiarly appear in the season's lines although the really good floral designs of one season could be counted on the fingers of one hand.

Within the last year or two the reign of the frieze has perceptibly drawn to its close. At one time considered a sine qua non in every room—in fact almost as essential as the furniture—it is now relegated to the cheap parlor combinations as they are called, where ceiling frieze and wall are beautifully matched, saving brains and much anxious thought to the dealer and the buyer. Wall papers are now usually carried to the ceiling or cornice and finished at the top with a picture moulding. Ceilings if good are painted or tinted, if cracked are papered with something simple in design and of almost one color. Sometimes the ceiling color or paper is brought down a short distance on the wall to meet the wall paper at the picture moulding. Sometimes the upper third of the wall is covered with a different design from the lower two thirds, the picture moulding again acting as divider. A very pretty treatment for bedrooms is to carry a narrow border around each wall of the room forming them into large panels. These borders frequently have corner pieces to match. Papers with the texture of burlaps, denims, &c., make a very good lower wall and are an excellent background for pictures. Ingrains or cartridge paper are now very little used. Pressed or raised papers except in leather effects are not much in use, good coloring being preferred to their somewhat showy effect. The stripe designs which come to us at present in such abundance will not continue to occupy so large a place in dealers' collections, yet they have an important use in giving an appearance of height to rooms whose ceilings are undesirably low, besides being an agreeable change from the ordinary run of designs. The old cretonnes and chintzes furnish a range of beautiful patterns for bedrooms, morning rooms, etc.

The proper treatment for all of these patterns is to simply cover the wall with them as would be done with the actual material.

Coming to the woodwork of the room we find a variety of new tones for natural wood. Rich browns, deep mossy greens, Flemish oak finish, may be applied to ordinary pine or white wood with highly satisfactory results. The strong reds and greens of the wall at once call for special treatment of the woodwork and these deep tones are the result. In direct contrast are the white and ivory tones which set off equally well the reds, greens and blues of the wall. The old fashioned drawing room in white and crimson or green is very much in evidence at present, while in the bedchambers white woodwork prevails, almost to the exclusion of everything else. Graining, while not tabooed on aesthetic grounds as formerly does not seem to find a place with other prevailing features. Oak among hardwoods is in great favor but more frequently finished in Flemish, Log] oak coloring, than in the natural wood.

One of the most desirable importations of old world ideas is the more general use of hardwood floors. Very few realize the danger to health which lurks in the harmless looking carpet which in many cases remains securely tacked to the floor for several years. An analysis of the dust accumulated in that time has revealed possibilities of disease which in many cases must have neutralized in the actual thing.

A permanent floor may be laid in any house on top of the existing floor without alteration to doors or other woodwork of the room and at the cost of ordinary carpet. Parquetry designs add decorative character to this part of the room. Not the least important advantage gained by the use of hardwood floors is the introduction of the very artistic and everlasting Eastern hand made rugs which now adorn so many of our homes. When the life of these things is considered, the money expended upon them is probably the best investment possible in house furnishing.

THE CHARACTER OF SAND GRAINS.

It has been pointed out by Sorby and others, that by the aid of the microscope much may be learned concerning the history and character of sand grains. He has classified them into five groups, which, however, graduate into each other. These are:—

1. Normal, angular, fresh-formed sand, such as has been derived almost directly from the breaking up of granitic or schistose rocks.

2. Well-worn sand in rounded grains, the original angles being completely lost, and the surfaces looking like fine ground glass.

3. Sand mechanically broken into sharp angular chips, showing a glassy fracture.

4. Sand having the grains chemically corroded, so as to produce a peculiar texture of the surface, differing from that of worn grains or crystals.

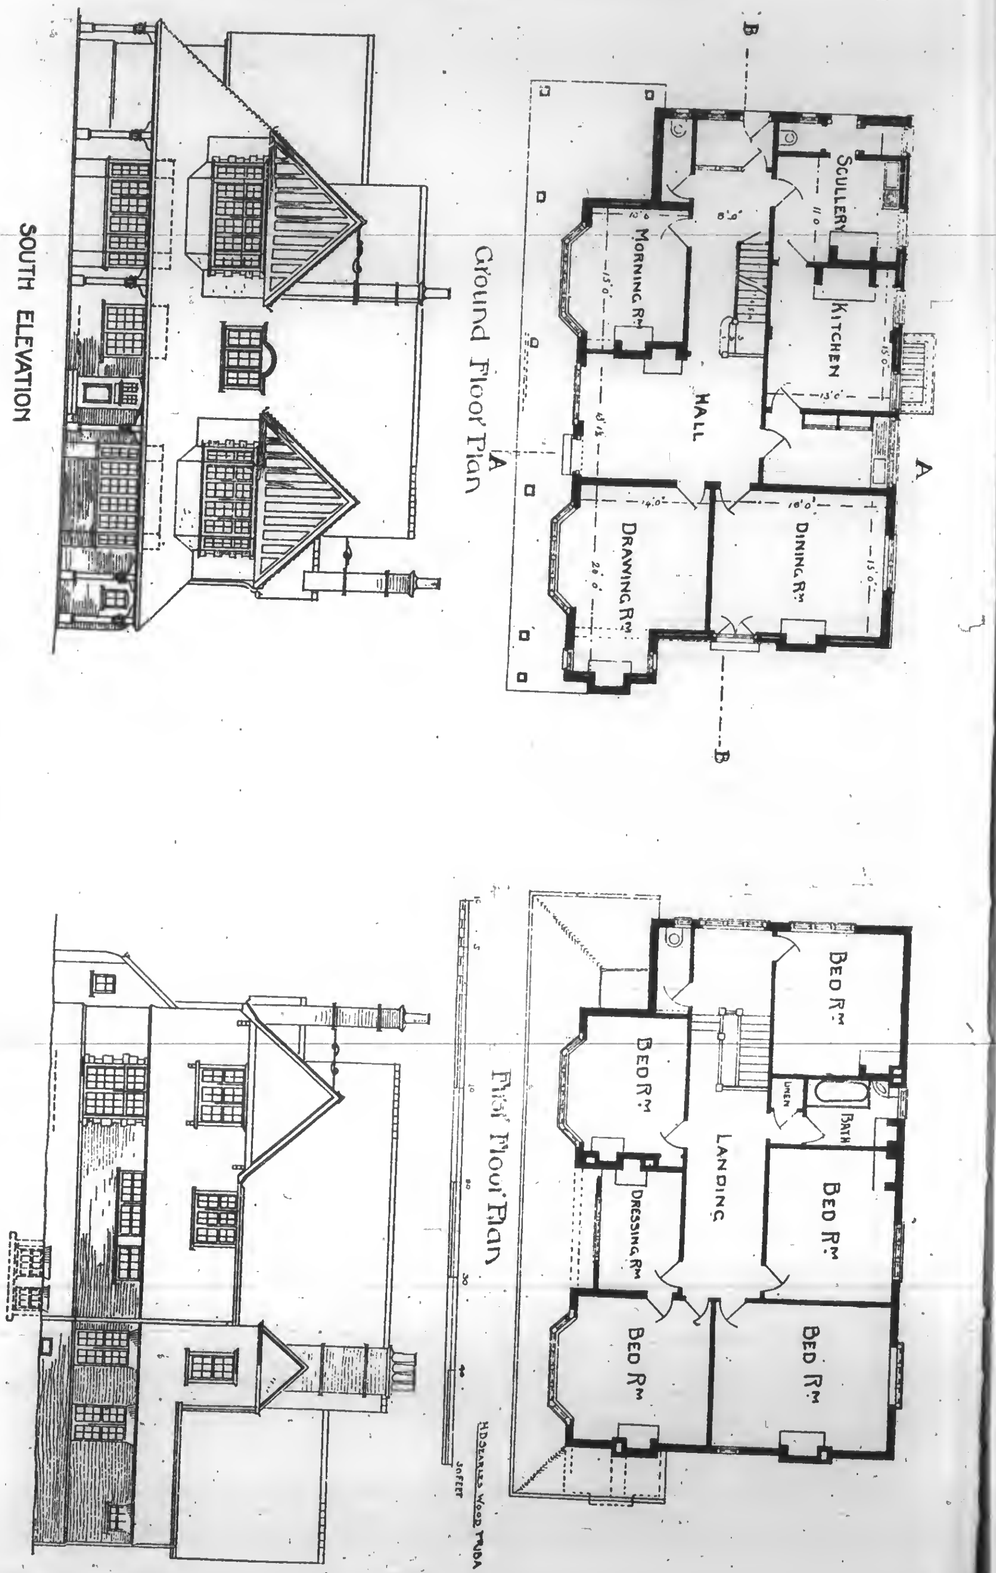
5. Sand in which the grains have a perfectly crystalline outline, in some cases undoubtedly due to the deposition of quartz upon rounded or angular nuclei of ordinary non-crystalline sand.

In the manufacture of bricks fired at a low temperature, No. 3 above described is no doubt the best, as it possesses certain binding qualities; but the usual type of sand met with in ordinary brickyards is either No. 1 or No. 2.

NOTES.

The value of building permits issued to date by the Inspector of Buildings of Winnipeg is $630,575, as compared with $383,633 for the same period last year.

The annual convention of the American Society of Civil Engineers opened at Niagara Falls, on the 25th inst., and will close on the 28th inst.



SMALL SUBURBAN HOUSES.
(Illustrations accompanying paper by Mr. Searles-Wood before the London Architectural Association.)

MONTREAL CORRESPONDENCE.

INSURANCE RATES.

The result of the refusal of the property owners to sanction the expenditure for improved fire equipment seems likely to be a further increase in insurance rates. At a recent meeting the Canadian Fire Underwriters' Association adopted the following resolution :—"Resolved, that the association records, with regret, the non-acceptance by the property owners of the recent proposed by-law for the improvement of the fire brigade and appliances and the consequent inability of the city to remedy, even in a modified form, any of the defects detailed in Inspector Howe's recent report on the city's fire brigade and appliances. The attention of the company is drawn to the matter with a view to considering whether the rates now obtained are adequate to the hazard." The Association appointed a committee to consider what action should be taken.

QUEBEC CONCILIATION AND ARBITRATION ACT.

An Act respecting Councils of Conciliation and arbitration for settling Industrial Disputes, passed the Quebec Legislature on March 28th. Its provisions are quite similar to those of the Ontario law of 1897. It provides for a Council of Conciliation consisting of representatives of the parties to the dispute ; and a Council of Arbitration a body of a more permanent character, which may, upon application of one of the parties, hear cases which have been before a Council of Conciliation without being settled, or, upon application of both parties, hear cases which have not first gone to the Council of Conciliation. The award of the Council of Arbitration is not binding, excepting with the assent of the parties. The failure of the parties to accept the award does not, however, prevent a further reference to a Council of Conciliation.—The Act applies to all employers employing not less than ten men in the same business.

P. Q. A. A.

At the special meeting of the P.Q.A.A. held on the evening of the 8th ult. there was quite a large attendance, among those present being noticed Mr. Tanguay from Quebec, Messrs. Venne, Archibald, Brown, M. Perrault, A. T. Taylor, Doran, E. Maxwell, W. S. Maxwell, Raza. Resther, Saxe., Lacroix, Monette and others. There was considerable discussion on the new tariff of charges and several strong objections were made by some of the members, but the following resolution was finally adopted : "That a vote of thanks be tendered to Mr. Maurice Perrault for the trouble he took to obtain the tariff for the P.Q.A.A. but we trust it will be amended as soon as possible."

The clause which met with opposition was

On all classes of buildings, costing from $50,0000 to $150,000 four per cent.

On all classes of buildings, costing more than $150,000 three per cent

The tariff formerly did not vary on account of the amount spent—only on the class of buildings. We presume the law is intended to read "for the first $50,000 at 5 per cent. for the next $100,000. at 4 per cent. and above that figure at 3 per cent." otherwise there will be the absurdity and injustice of an architect's commission on a building costing say $48,000 bringing a higher remuneration than one costing say $51,000.

NOTES.

As Mr. Owens is now one of the city's assessors, he has been obliged to give up his business as painter and decorater, and has therefore sold out the good will to his foreman, Mr. Houte.

A fire recently broke out in the offices of the Mount Royal Cemetery Company. A new building is already being built larger and more convenient from plans by Messrs Hutchison & Wood.

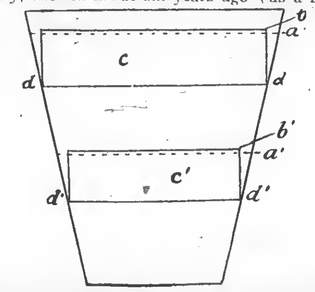
The building materials of the old St. Anne's and St. Gabriel Markets were sold on the 13th ult., so that these old city relics are a thing of the past. They have for many years been carried on only at a loss to the city so that we imagine there will not be many tears shed at their departure.

As Royalty is intending to pay Montreal a visit shortly it is trusted that some attempt will be made to put the streets in better repair abd also that owners of property will do their share in, putting a new coat of paint on the front of buildings in good order. It is wonderful what a well kept grass plot in front of a house adds to the general appearance so that it is well for architects to bear it in mind.

BRICK IMMERSION TESTS.

One of the greatest difficulties that experimenters on the different physical properties of bricks have had to contend with says a writer in the British Clayworker, is that connected with absorption. The older experimenters used to place the brick under an air pump, and having (as they thought) exhausted all the air from it, they proceeded to immerse it in distilled water. All of which is a careful and cautious proceeding, no doubt, but which had subsequently to give way to the exigencies of practice. Then engineers came along, with rough-and-ready ways and no time to spare, and they simply shot the brick into a tub of water, weighing it before it went in and after it came out—the difference, they held, indicating the porosity of the brick. On second thoughts, both they and the few architects who then took an interest in the subject, began to form the belief that the element, time, ought to be taken into account ; but they came to the erroneous conclusion that the longer a brick stayed in the water the more water it absorbed. At about the same period, the chemist announced that bricks contained, as a rule, a considerable amount of matter which was soluble in water, so that the absorption tests ought to be considered pari passu with loss of solvent material, when weight only was to be employed as a criterion of absorption. In other words, there was waste, they said, as well as absorption.

The present writer, who in his time has tested the absorptive capacities of different kinds of bricks throughout the country, shewed about six years ago (as a result on



over 400 different bricks) that none of the methods then in vogue gave accurate results. At a very early stage in his work he discovered that when a brick was placed under water it was increasingly difficult for the air to escape from the pores of the brick as the depth of water above the brick was increased. The same brick placed in water three feet in depth gave a different result to the same when only immersed six inches. So, therefore, he devised a plan, which has proved highly satisfactory, that of leaving one of the long narrow edges of the brick just above the surface of the water—the remainder of the brick being immersed. The intrusion of the water into the brick on its immersed sides tends to expel the air from the free surface above the water, and thus there appeared a possibility of arriving at a standard method of testing. And the writer is of opinion that this is the most accurate method of testing absorption.

His further tests, however, have shewn him that there was something lacking, in that the bottom of the brick always rested on a flat surface, and thus precluded the water from having free access to that portion of it.

As a consequence, he has devised a method which, so far as he is aware, is new, though it seems so simple that it is possible another experimenter may have thought of the same thing. This method is illustrated in the accompanying diagram. The vessel containing the water is bucket-shaped—wide at the top and narrow at the bottom. It is designed to take both large and small bricks. Let a represent the water level, c the brick, and b the surface of the brick just projecting above the water. It will be obvious that the only parts of the brick which touch the sides of the containing vessel will be situated at a, so that the water has free play, to enter the bottom and sides of the partially immersed brick.

When a smaller brick is being dealt with it is necessary to lower the water level, so that the relative positions are a, b, c, d, as shewn in the diagram.

It is necessary in these experiments to put in more water to compensate for evaporation during long-time tests and any waste (as from a rubber) should be carefully noted. Where necessary a chemical examination of the water at the end of a test may be made, to discover if the brick has suffered from dissolution by chemical means. In practice, however, the latter will not often be found necessary, as the difference in actual absorption by the improvements brought about by this new method is sufficiently well marked to tell its own tale.

ACCIDENTS TO RESERVOIR DAMS.

By C. Baillargé, Mem. Am. Soc. C. E.

The late washout at the reservoir dam at Middlefield, Mass., and that at Chicoutimi, Que., can only avail as lessons in "The Instructiveness of failure" when the way in which they occurred can be made known to the profession.

True, it has been shown that in the Middlefield case, where the dam was but 20 feet high, and the level of the spill-way 15 feet, the gates over the spill-way could not be opened due to their faulty construction and that the water rose till it poured over the dam and caused its destruction; but how the erosion could have caused the wreck is not explained, in view of the fact that between the outer walls of the dam which was 30 feet in breadth and abundantly heavy and strong to resist any pushing or forcing of the dam forward as at Boazey in France, Austin in the United States and ealsewhere, there were two intermediate bulk heads or walls of 2-inch matched sheet piling on boarding.

No gradual erosion from the top downwards could therefore have occurred on account of these intervening water tight partitions. The only way then of explaining the washout through and through the dam, is this: the overflowing water, first wore away the outer, lower or down stream of the three vertical sections of earth work into which the dam was divided by the bulk heads, taking with it the rubble work of the revetment wall, the component stones from which were found as far as 500 feet down the river.

When this outer or lower portion of the dam had crumbled away, the lower of the two bulk heads followed suit, after which the over-pour of water immediately attacked and scoured away the middle section of the earth work, followed by the overthrow of the upper or inner bulk head, and this by the immediate cutting through and down, by erosion, of the inner or up-stream suction of the earth filling with its protective wall of dry rubble.

Where a portion of the clay filling was resistent enough to hold its own against the scour, up to a certain height from bottom level of reservoir, the portions of the bulk heads above that level, were of course broken off at level of top of remaining clay by the direct pressure of the water behind them.

The Middlefield mishap is therefore a case not of the bursting of a dam, not of a bodily pushing away of the dam as at Austin, but one where the dam failed, as do the levees along the Mississippi, by erosion of the water from above downwards.

We shall now see that the accident at Chicoutimi is a case of erosion from below upwards. The dam across the Chicoutimi, which is one of the out-flows or discharges from Lake Kinogami and its smaller companion as expressed by the diminutive "Schish" Kenoganischish, is about a mile from the city or town of Chicoutimi, the Metropolis of the Saguenay District.

The dam is built at right angles across the stream, a powerful one empting into the Saguenay river. It is a wooden structure of crib work with a base up stream of about 3 to 1, planked over with a water tight flooring and relying for its stability on being kept down and in situ by the very weight of water above it, some 20 feet higher than on the down side, and though, the higher the water within the reservoir the greater the thrust outward or downward, the greater also the weight upon the dam and its adherence to the bottom on which it rests and is probably bolted to.

Above the dam proper is a superstructure some 10 feet or more in height answering as a bridge or roadway between the opposite sides of the river and to the upper or up stream side of this superstructure are adapted a series of some 20 gates or more, but which, as at Middlefield, must have been inoperative due to their great size under a head of some 10 feet of water against them: for the water on the occasion of the accident about to be related rose to 19 feet above its normal freshet level and evidenely pressed hard against the dam superstructure which is entirely too narrow, it being but 12 feet wide instead of 20 which it should have been; and to proof, it is now bulged down stream, wriggled and out of plumb as well as out of line.

Now while this dam of some hundreds of feet in extent across the river was solidly abutted against the river's high and rocky bank at one or its eastward end; the western end of it rested on or a few feet into the face of a bank of quite a different nature on the opposite side; where not only does the rock rise to or crop out at level of bed of river; but the material above it and for a height of some 50 to 60 feet is nothing but the most irresisting soft clayey sand and vegetable mold.

Had the precaution, an expensive one of course, been resorted to, as was done at Grand Mére on the St. Maurice, in an absolutely similar case, of rip-rapping the face of the cliff from the dam to some distance up stream or of a wooden revetment against wash and scour of river, the accident likely might not have happened. It would certainly not have occurred had this cliff revetment been made water tight to a certain height, even though it should have cost an extra $20,000 or more to do so along a stretch of 200 to 300 feet.

What happened is this: the water having on the occasion risen to 30 feet, a pressure of 13 pounds to the square inch or close upon 2,000 lbs. to the foot, a great tendency to filtration through the bottom of the bank (where the strain was irresistible by material of the light and loose structure alluded to) was brought about, and a leakage through and around the western end of the dam was seen to occur. Under such pressure and through such friable material it may easily be imagined how quickly the scour did its work, increasing in a few hours the water way through the bottom of the bank to the dimensions of a sewer and then enlarging sidewards and from below upwards, to the vastness of a tunnel, when of course the roof or over-lying earth caved in—the out rushing water in the mean time wearing away the side hill from below and causing the cliff to go piece by piece almost vertically in slices from 4 to 6 feet thick at a time, till the gap up stream from the dam reached to a distance of some 200 feet, while in the direction of the length or axis of the dam prolonged, the hill was cut into by not less than 300 feet and the scour down stream or below the dam wore away the bank of the river to a distance of more than 700 feet.

The quantity of material carried away—the cliff as already stated being some 60 feet high—is not less than 300,000 cubic yards discoloring the water of the Saguenay for miles below the town and rendering it for the time being unfit to drink.

The dam will of course now have to be extended by some 300 feet or more to the opposite bank or to the present site thereof, while a temporary dam will have to be built to confine the water to passing over the present dam till the extension is put in; but the whole structure should be widened out down stream by say 20 feet, to support a bridge and gate superstructure of some 25 to 30 feet in breadth and capable of holding its own against any subsequent rise of like magnitude in the river; and this should be done at any cost and in the the company's own interests; for as the area of the reservoir or breadth of water upheld will hereafter be of so much greater an extent westward, a second accident of the kind might sweep down upon the city and destroy thousands of dollars worth of property, with probably or at any rate possible loss of life for which the company might be held responsible—and a stitch in time saves nine.

I would also say here in relation to the new concrete dam at the Chaudiere—it was quite a question this spring whether it would not give under the immense ice pressure against its almost vertical inner or upper face, and my surmises of last fall when writing on the subject have now become a certainty, and to the effect that inward of this concrete rampart should be made an inclined apron of crib-work of two or three feet of base to one of height boarded over with deals or plank laid parallel to the flow of water, and such that any future tendency of an ice jam against the dam will be done away with by the certainty that the swell of the ice forward or down stream will shove it up the incline and topple it over the dam in a way to do no damage to the permanent structure.

THE CLASSIFICATION OF ROMANESQUE ARCHITECTURE.*

By Francis Bond, M. A.

The subject of the classification of the Romanesque styles was a large one, and could only be dealt with shortly within the limits of his paper. Classifications already existed—those of De Caumont, Quicherat, Viollet-le-Duc, and particularly Anthyme Saint Paul, were referred—but they helped one but little forward. It remained to consider whether a wider basis of classification could not be found—one resting on the main facts of plan and structure.

First of all, what was the one thing that the old builders—whatever the schools they belonged to—were trying to do? With the exception of a certain number of them who were attempting to solve the church-building problem by following the type of St. Stefano Rotondo at Rome or of St. Vitale at Ravenna, and whose further outposts, with the exception of the churches of the Knights Templars and the Knights Hospitallers, are to be found in the churches of Aix-la-Chapelle, Ottmarsheim, and Germigny-des-Prés, all the builders of Western Europe, from the ninth century, when Romanesque architecture commenced, to the twelfth century, when it was superseded by Gothic, were engrossed with one supreme problem—how to vault a basilica. This was the master problem of the builders of the Middle Ages from the end of the ninth to the middle of the twelfth century. The amount of engineering skill, the ingenuity, and the variety of the solutions proposed were astonishing. They seemed never to have had their full due. Gothic architecture got nearly all the credit. As a matter of fact, every single one of the main difficulties inherent in the task had been effectually met—and met in more than one way—before the first Gothic architect ever handled a trowel. Early in the twelfth century, or before, at least five complete solutions had been arrived at, as may be seen at Le Puy, Tournus, Cluny, Speyer, and Durham.

The problem how to vault a basilica meant—(1) that there were to be aisles as well as a high nave; (2) that some form of vault construction was to be devised; (3) that since a vault of stone was heavy, piers must be substituted for graceful, but weak, classical columns; that the thrusts of the high vault of the nave must be stopped in some way by abutment in or above the aisles; (5) that top-lighting by clearstory windows was to be retained; (6) that the outer surface of the vault must be protected from the weather.

(i.) In most cases one or more of these conditions were evaded. One school—the most ancient of all which held the whole of the field till the ninth century—simplified the problem by omitting the vault and retaining the colonnade.

(ii.) A second solution—also very incomplete—was to omit the aisles; to build a hall-church roofed with a tunnel vault. This simplified the question of supports, for it substituted solid walls for hollow arches; any amount of clearstory light could be introduced, and the walls could be thickened to any extent to provide continuous abutment to the thrust of the great tunnel vault. Everywhere it was the natural and proper solution where only a small church was required, but it was employed in Provence even in churches of cathedral rank.

(iii.) A third method, represented by the school of Périgueux, also removes the difficulties of supports, abutment and top-lighting by eliminating the aisles. It presents us with another variety of hall-church, roofed, not with a tunnel, but a row of domes, and it is to be noted that the corners of each square bay of the nave are filled in with pendentives to support the dome.

(iv.) The next method is found only in the church of Loches, near Tours. Originally there was a low tunnel-vaulted nave, with aisles, of the 11th century. But about 1160 the eastern portions of the nave were pulled down, two square bays were formed, and on these bays two spires were erected.

(v.) In two churches of the first rank a row of domes was employed to roof an aisled nave. The nave was spanned by a series of strong arches. These were so placed as to divide the nave into square compartments. On each square an octagonal dome was poised, the corners of the square being filled up with corbelling or squinches to afford support all round to the base of the dome. The typical example of this is the wonderful cathedral of Le Puy, the nave of which is roofed by a row of six domes on squinches.

(vi.) The next method may be distinguished as the arch-and-lintel system. Strong transverse arches were built across the nave about 9ft. apart; a wall was built on each arch rising up to the apex of the arch, and then lintels of basalt were laid longitudinally—i.e., from west to east. Count Vogüé has fully illustrated this curious phase of architectural history in "La Syrie Centrale."

(vii.) We next come to a whole series of attempts to solve the problem by covering an aisled nave with what is called a tunnel, waggon, barrel or cradle-vault. Of these the most scientific is that of Tournus Abbey church. As in the churches of Syria, the nave was spanned by stout arches, each arch carrying a wall. But each pair of these walls, instead of carrying lintels, as in Syria, carries a short tunnel set transversely.

(viii.) We now come to the vast number of churches in which the tunnel-vault of the nave was placed longitudinally—i.e., in the direction of the axis of the church. The naves vaulted with longitudinal tunnels may be divided into those (a) where the tunnel rests on a pier-arcade; (b) where the tunnel rests on the arches of an upper vaulted aisle; (c) where the tunnel rests on a wall pierced with clearstory windows.

(ix.) Such interiors as that of Notre-Dame de Poitiers were painfully low. It would have been dangerous, however, to raise the tunnel much by increasing the height of the piers. So in Auvergne especially, the expedient was hit upon of building two aisles instead of one, both vaulted; then the tunnel could spring at a much higher level. Moreover, some of the gloom of the Poitevin type of nave could be dispelled by piercing the back wall of the new upper aisle with windows.

(x.) The first step to carry out the one unfulfilled condition in the problem—the provision of clearstory light—was taken by piercing the base of the tunnel itself with clearstory windows. The final step—a most important change—was to insert the windows wholly in a clearstory wall. This latter seems to have been accomplished independently in the south, in Provence and Languedoc; in the north, in Burgundy. The clearstory was already in use in tunnel-vaulted churches in the eleventh century at Saint Guil, Helm-du-Désert in the Southern Cevennes, and in Burgundy on a small scale at Saint-Benôit-sur-Loire (commenced 1089.)

(xi.) This solution, which was destined, with a generation or two, to culminate in the Gothic architecture of Saint-Denis (1140), consists in covering a nave with unribbed groined vaults.

(xii.) The final step was to substitute the ribbed for the groined vault, to dispose the vaulting compartments of the nave in oblongs, to facilitate the vaulting of these oblongs by the application of the pointed arch, and to transmit the thrusts of the high vault by means of flying buttressess to the buttressess of the aisle walls. To this, Gothic architecture added three developments: (1) It weighted the buttresses with pinnacles; (2) to a large extent it replaced the masonry of the walls by glass; (3) in Durham nave, the Abbaye-aux-Dames, and elsewhere, abutment was isometimes provided by flying buttresses disposed beneath the aisle roof. In Gothic the flying buttresses are placed above the aisle roof.

(xiii.) This method, which consisted in omitting the vault, was no solution at all. The nave is not constructed in genuine basilical fashion, as in the first method, but is built as if a vault were intended. The home of this unworthy construction is Normandy.

Of the foregoing solutions of the vaulting problem, the third, the employment of a dome resting on pendentives, is by itself a full and satisfactory criterion. It occurs nowhere except in a group of some thirty-five churches in the district of Périgueux, with such "outliers" as Fontevrault and Angoulême. No. 2, the hall-church, is most

*Abstract of paper read before the Royal Institute of British Architects.

common in the south-west and south of France, from Poitou to Provence. It may be vaulted either with a longitudinal tunnel or with groined or ribbed vaults. No. 8, where a tunnel vault rests directly on the pier arches, occupies much the same districts as No. 2. No. 9, where the tunnel rests on the arches of an upper aisle, extends from Clermont-Ferrand, in Auvergne, to the south-west as far as Conques and Toulouse. No. 10A, where the tunnel is combined with a triforium and clearstory, is the final development reached in Burgundy. No. 10B, where there is tunnel and clearstory, but no triforium, is the solution of Provence and of Piedmont. No. 12, the ribbed vault, occurs sporadically, except in Germany and Lombardy, where it is characteristic. No. 13, the unvaulted nave, was nearly universal in Normandy and England till the twelfth century was well advanced.

The author went on to consider how these eight divisions will stand other tests. A very important test is afforded by the planning of a church, especially of its eastern limb. It must suffice to trace four main types of choir-plan. The first is that with three parallel eastern apses, of which there is a variant with square-ended aisles, as at Cerisy-la-Foret, and another with aisles square externally and semicircular internally, as at Romsey. This is pre-eminently the plan where the unvaulted nave prevails, viz., Normandy. It is frequent in Lombardy and in those Provencal churches that have aisles. A second plan is that of the ambulatory and "cheviot." It is rare in Germany, Lombardy and Provence and non-existent in Normandy (excluding England.)

The plans alone, apart from other considerations, would entitle Germany to rank as a distinct architectural province. In Provence the aisled churches generally have three parallel eastern apses.

The divisions may be tested again by the treatment of the central tower: (1) its vaulting; (2) its shape whether square or octagonal.

The Romanesque builders had three forms of vault at their disposal in the eleventh century; the groined vault, the tunnel vault, and the dome. The most difficult problem they had to cope with in vaulting was the question of putting a vault over the crossing, resting not on walls, but on four unbuttressed legs. They had hardly dared yet to put a groined vault over their naves, fearing its concentrated thrusts. Their favorite tunnel vault could not be used at all at the crossing, for it needed solid walls for its support. They had perforce to use the dome, in all cases, except in the Périgueux district, resting on squinches. Secondly, they had to stop the thrusts of this dome by carrying up a central tower to weight the arches or walling on which the dome rested. As regards the shape of this tower, they had two alternatives. The crossing was square, and so the tower over it might be square, as was the great central tower of Cluny and that of Tournus But the squinches reduced the square of the crossing to an octagon; and as the tower rested directly on the octagon and not on the square, it was more natural that the tower also should be octagonal. Hence that magnificent series of octagonal central towers in Burgundy, and Southern France, Germany, and Lombardy, culminating at Mayence and Saint-Sernin, Toulouse. In Normandy and England, on the other hand, the builders hardly ever dared to vault their naves at that early date, and never the crossing. And there being no dome in an Anglo-Norman tower, it is square.

Another test is afforded by the grouping of the towers. (1) The glorification of the tower reaches its highest pitch in Germany. Six towers are found at Speyer, Worms and Laach, seven at Limburg. (2) In Burgundy the magnificent tower group of Cluny seems to have remained without a rival. Its daughter churches were satisfied with at riplet; an octagonal central tower and two square western towers was the favorite arrangement. The towers had several stages, similar in form. (3) In Normandy also the triplet was the favorite, but the central tower was square, and not domed internally. (4) In Poitou the characteristic is the conical spire "en pomme de pin," which often surmounts the tower. (5) In the Périgordian region is seen the same conical spire, together with the characteristic cupolas. (6) In Provence "a simple square tower is commoni with a very low spire." But some have central octagons. (7) In Auvergne a specially characteristic arrangement is that of a square western tower in the centre of the facade and a central octagon. (8) In Northern Italy the campanile type greatly predominates, and where the massive Romanesque tower is found, it is usually divided (in campanile fashion) into very numerous stages. Nowhere, except in the Como churches, does the campanile form part of the structure of the church; often it is quite detached.

We may discriminate the following eight schools of Romanesque: I., the Périgordian; II., the Poitevin; III., the Provencal; IV., the Auvergne; V., the Burgundian; VI., the Norman; VII., the German; VIII., the Lombardic.

As regards the above classification, one word of caution is necessary. In speaking, e.g., of the style or school of Auvergne, it is not meant that all the churches in Auvergne were built in this style, or that there were no such churches outside Auvergne, but merely that such churches were more common in Auvergne than elsewhere, and may therefore for convenience be described as belonging to the style or school of Auvergne. Also that those features described as characteristic were not invariably found; they were merely those which occurred most frequently.

One is tempted to try to work out the relations to one another of the different schools. Certain resemblances are patent. The super-imposed aisles link the style of Lombardy to that of Auvergne; German Romanesque is connected with Lombardic on the one hand, and with Norman on the other. But a much more exhaustive classification is necessary before any results of lasting value are likely to be obtained.

Still stronger is the temptation to enquire into the origins of all the Romanesque styles, whether they are derivatives, as some have held, from Provence, or as others have held, from Lombardy. Such architectural pedigrees are not, as a rule, trustworthy. And there always remains an alternative hypothesis, which seems to have within it much of truth, namely, that the styles were none of them mainly derivative, but that the same problem was engaging all the different regions more or less simultaneously; that the builders of each region were solving it, with some little light, indeed from their neighbors, but mainly independently, by empirical experiments of their own, aided by the survival here and there of traditions of Roman construction, and by the study of local Roman monuments.

Another caution requisite is that the classification does not cover the whole ground. This is necessarily so. Between each region and the next there was always a debatable ground, where two or more styles would be in simultaneous use. Indeed, a "pure" region would be the exception; the greater part of the area of any one country would employ mixtures of style. England is an instance.

It had always been customary, the author believed, to regard the Romanesque of England and Normandy as one. The Romanesque of Normandy, however, seemed to be a "pure" style, and that of England a "mixed" style. While by far the most important factor is the influence of such pre-Conquest churches as Bernay, Jumiè, and the Abbaye-aux-Hommes, we must also attribute some degree of importance, at any rate in the planning, to the highly developed Romanesque of Auvergne and Burgundy.

THE ONTARIO ASSOCIATION OF ARCHITECTS.

The walls of the O.A.A. Rooms have recently been adorned with a number of excellent photographs of interesting Architectural works in foreign lands.

In exchange for a copy of its proceedings, the Association is now receiving regularly the publications of the British and American Architectural Societies—also French, Italian and other Foreign Architectural periodicals.

The weekly luncheons held in the Association rooms every Tuesday have been well attended, and very enjoyable and profitable. They have served to promote acquaintanceship among the members, and afforded opportunity for the discussion of many subjects of interest to the profession.

STUDENTS' DEPARTMENT.

PORTLAND CEMENTS.

Portland Cement has been defined by the Association of German Portland Cement Manufacturers as the product of the burning to the point of sintering, and subsequent grinding to a fine powder of certain materials in definite proportions, chiefly carbonate of lime and clay. These raw materials are ground and mixed in either the dry or wet process according to their character—if the dry process is used the mixed materials are moistened and molded into bricks. In the wet process the bricks are made from the wet material after it has been reduced to the proper consistency. These bricks are dried and then burned in suitable kilns to nearly a white heat. The resulting "clinker" is then ground to a fine powder, i.e., the cement.

In the rotary kilns the material is introduced into the kiln in the form of dust or a liquid "slurry" and issues from the kiln continuously as burned clinker. The expense of drying, charging and emptying the kiln is thus saved. By the rotary process furthermore the output is double that of the continuous vertical kiln.

In vertical kilns the raw material has to be molded into bricks dried and then charged into the kiln with alternate layers of coal or coke.

Portland Cement is distinguished chemically from natrral cements in that it has a far larger proportion of l me, it must be either free, or nearly so from Magnesia; the temperature at which it is burned being necessarily much higher there is little or no Silicate left undecomposed; it must contain only a small percentage of Iron-oxide to prevent fusion of the material at this temperature.

The following comparison of the chemical analysis of a good Portland Cement with two Natural Cements of the Lime and Magnesia class will no doubt be of interest:

	Portland	Natural	
		Lime	Magnesia
SILICA	21.6	21.7	16.9
ALUMINA	7.4	8.3	11.0
IRON OXIDE	2.3	4.1	4.6
LIME	62.8	56.6	34.6
MAGNESIA	1.5	2.8	14.8
SULPHURIC ACID	1.3	1.3	1.0
ALKALIES	1.5	.0	1.8
IGNITION	2.4	8.2	4.8
SILICATES UNDE	.0	8.0	12.4

The Carbonate of Lime necessary may be Chalk, Limestone or Marl. If chalk is used it is mixed in water with the clay to a creamy consistency usually called "Slurry."

Limestone, unless it contains nearly the necessary amount of clay, has to be ground very fine in order that it may mix perfectly with the clay, so that wherever possible, Limestone is used that contains sufficient clay in order to obtain a perfect mixture by grinding only.

Portland Cement is manufactured chiefly in Germany, the United States, England, France, Belgium and Canada and is by far the most valuable of all the elements It usually consists of about 62 per cent. of lime, 22 per cent. of silica and 7 per cent. of alumina, (2 per cent. above or below these figures is the limit) together with small percentages of magnesia, oxide of iron, etc. A very slight difference in the manufacture of the material or in the chemical composition of the material itself may take considerable change in the value of the resulting cement, so that it is very necessary to resort to rigid testing if the best cement is required. The American Society of Civil Engineers recommends that tests be confined to methods for determining Fineness, Liability to Check or Crack and Tensile Strength.

As to fineness of grinding it may be stated that the coarse particles act practically as sand, and it can be taken as a rule that the finer the cement, all else being equal, the more the sand that can be mixed with it.

Fine grinding has the effect of reducing weight as is shewn by the following table:

10%	residue on a 80 mesh sieve weighed			110 lbs.	per bushel
20%	"	"	"	116	"
25%	"	"	"	121	"
35%	"	"	"	123	"

As to the exact degree of fineness that is advantageous there is some difference of opinion, a 10 per cent. residue on the No. 100 sieve being the minimum test for fineness often advocated.

To test for soundness, that is liability to check or frack, a thin part of cement should be placed on glass, allowed to get hard in air, while covered with a moist cloth, and when submerged in water at 130 degrees Fahr., must show no signs of warping, swelling or cracking. It is characteristic of expansion cracks that they run from the edges toward the centre of the pat and are widest at the edges and narrower toward the centre.

The swelling of cement is always due to defects in manufacture. Cracks similar to those produced by swelling, are also produced when pats or briquettes are placed in water too soon, or before the setting is complete. To prevent this the test pieces are kept in moist air for 24 hours before placing in water.

The tensile test is commonly the one to which most attention is paid, but it is strongly recommended that "Sand Tests" be used as well as neat tests, and furthermore that attention be paid to the proportion of the increase of strength at the various ages. The annexed table gives the results of the tests of cement used recently by the city of Toronto and made under the direction of Mr. Cecil B. Smith.

Brand of Cement.	No. of Samples Tested	Average Specific Gravity	Result of Blowing Test	Residues % Sieves Meshes Per Inch 50	74	100	Tensile Strength Neat 1 week	1 mo.	2 mos.	3 mos.	6 mos.	Tensile Strength 3 to 1 1 week	1 mo.	2 mos.	3 mos.	6 mos.

The specific gravity test is a delicate laboratory test and is one requiring a high degree of care. The object of this test is to determine the density of a cement, that is the sufficiency of the burning, or in other words the soundness, so that the hot-bath test is sufficient.

It is in the power of the manufacturer to produce either a quick setting or a slow-setting cement. A cement which requires two hours or longer to set is called slow-setting and is preferred when it can be used, on account of its greater strength. Soda has been found to produce a marked acceleration in the setting, when added to the neat cement in the proportion of about 1 1-2 per cent but the addition of the soda has the effect of reducing the strength slightly.

For relative values of Portland and Natural cements see tests and remarks under Natural Cements.

The only safe way for an architect to arrive at the value of a cement is to have it tested in a well-equipped cement testing laboratory, where accuracy and proper conditions are scrupulously observed.

From the above remarks it will be gathered that quality in a Portland Cement depends chiefly :—

1. On the proper propoetions of the constituents.
2. On the proper degree and manner of Calcination.
3. On the degree of fineness the "Clinker" is ground.

The market for Portland Cement is increasing very rapidly and the better the material is understood the greater seem the chances of its being used more extensively. The world's production of Portland Cement has been estimateh at 45,000,000 barrels, of which Germany produced about 19,000,000 barrels and the United States over 7,000,000 barselsi The exports in 1898 were as follows :—From Germany 3,096,234 barrels ; from Belgium, 2,495,370 barrels ; from United Kingdom 1,958,550 barrels.

The increase in the production of Portland Cement in the United States in the past 10 years has been most phenomenal, as can be easily seen by the following table :— In 1891, 455,000 barrels ; 1894, 798,000 barrels; 1897, 2,678,000 barrels ; 1900, 7,500,000 barrels. The Portland Cement factories are largely situated in the Lehigh Valley district and about 80 per cent. of the product is now burned in rotary kilns.

The market in Canada has not been large, but it appears to be extending. In 1900 there were 283,124 barrels of Portland Cement made in the Dominion, a large proportion of which is manufactured in the Province of Ontario: The home production is about equal in amount to the imports, and is mostly of a high-grade.

"SALLE DES FETES."

This class of building, which is the subject of designs by Mr. W. S. Maxwell, architect, of Montreal, in the illustrated pages of this number, is conspicuous by its absence in Canada and the States, and is intended for Concerts, State Receptions, Balls, Theatrical Representations, etc.

The floor of the large Hall would be removeable, so that when a reception took place the floor would be level, and when a theatrical representation was in progress this floor would incline towards the stage.

The front portion of the stage is removeable, giving the Hall the form of a true ellipse when so desired.

The first floor has a grand foyer over the main vestibule, and opening off the foyer is a gallery opposite the stage. Large galleries are reached by ample passages, and from the foyer one reaches the open loggia.

The main hall could contain an organ if so desired.

In designing this building the object kept in view has been the providing of a monumental structure, facing upon a Square, and having streets at either side.

THE ARCHITECTURAL LEAGUE OF AMERICA.

Messrs. J. P. Hynes and Wm. Rae, represented the Toronto Architectural Eighteen Club at the annual convention of the League held last month in Philadelphia. These gentlemen were successful in inducing the League to decide upon Toronto as the place of meeting next year.

NOTES.

Mr. Samuel Cabot, of Boston, is sending out to architects and others interested, a new color combination in his Creosote shingle stains.

Mr. W. G. Jones, treasurer, on behalf of the officers and office staff of the Pease Furnace Company presented a gold locket and chain to Mr. James M. Bell, an old and much esteemed employee, who has been appointed its representative in the west.

Four rules of Descartes are given by Viollet-le-Duc for the guidance of the architect. They are briefly : first, never to receive anything as true that cannot be proved : to avoid precipitancy and prepossession : second, to divide each problem into as many parts as possible, or as required for a complete solution : third, to follow a certain order, beginning with objects that are simplest and most easy, and ascending by degrees to the more composite : and last to make such a complete enumeration in every field of enquiry as to insure completeness.

SUGGESTIONS FOR DECORATORS AND FURNISHERS.

A handsome billiard room, decribed by Edward Hurst Brown in the Painters' Magazine, has the walls paneled with flat mahogany panels, scarcely sunk below the level of the stiles and rails. A broad frieze is carried round the room of mahogany, inlaid in a mosaic pattern with white holly. The ceiling is likewise of mahogany, inlaid with holly, the design being a series of rosettes for the border enclosed, in squares, inside of which is a chain pattern. The centre is divided into eight large squares, each of which incloses a large inlaid double circle, with small circles filling up the angles and an intricate interlacing pattern in the centre of each of the larger circles. A broad fire-place, with a border of blue tiles, it at one end of the room, flanked on either side by Ionic columns, which runs up to support the frieze that projects over the mantel shelf. The floor of polished red oak, that has been stained a deeper red, is covered with long Oriental rugs around the handsome mahogany billiard table that is severely simple in its outlines. Upholstered chairs in figured velours occupy the corners of the room, while along the sides are wall chairs with dark blue leather seats. In the window seat is a pile of bright-colored cushions, making it a comfortable place to sit and watch the game. There are no hangings, Holland shades serving to screen off the light.

A dining room in a New Jersey house, that is as much to be commended for its simplicity as for its good taste, has a high wainscot of two-inch moldings, stained with forest green, like all the other woodwork, and finished with a dull luster. A narrow shelf molding caps the wainscot, but is not used for the miscellaneous display of plates and jugs that one is so apt to find there. The upper portion of the wall is hung with a verdure tapestry, having dull green leaves and the large rose-pink flowers of the rhododendron. At the ceiling angle is a five-inch oak cornice molding. A raised plaster stiling about a foot wide runs round the ceiling, the central panel being sunk about an inch. The stile is tinted a deep ivory, while the panel is in ivory white. At one side of the room is a fire-place lined with green brick and faced with Sienna marble. There is very little furniture in the room none that is not necessary, and an entire absence of draperies, except white Holland shades, thus giving an air of spaciousness, lacking in the cultured up style of house furnishing that is usually popular. The heavy square dining table is of forest green oak, severely simple in its lines. The chairs are rush-bottomed, and the sideboard depends more on the good taste of its outlines and the silver and glass displayed upon it than upon any decoration for its beauty. Over the table is an electrolier with an umbrella drapery of flowered China silk, with deep fringe. At the door is a fourfold screen, with panels of stamped leather in bright colors, heraldic devices and quaint pictures of knights and ladies in the style of the old German masters. On the floor is a handsome Oriental rug in green and dull-rose-pink tones.

PERSONAL.

Mr. David Myers, the winner of the Rotch Travelling Scholarship this year, formerly resided in Toronto, Ont.

Mr. Ewart, architect of the Public Works Department, at Ottawa, is on his way to Europe for the purpose of inspecting, in company with Hon. W. S. Fielding, who is now in England, the Royal Mint, preparatory to the preparation of plans for the branch at Ottawa. Mr. Ewart will also visit Edinburgh and Paris, and on his return will inspect the more important public museums in the United States.

Mr. L. McG. Allan, a student in the office of Messrs. Gouinlock & Baker, architects, Toronto, has been awarded the gold medal given annually by the Ontario Government for the best example of drawing and design in architecture at the Central Ontario School of Art and Design. Mr. Allan has been attending the student classes conducted during the past winter by the Toronto Architectural Eighteen Club, and it was on the merits of the work done by him in connection with these classes that the medal was awarded.

AN EFFORT TO SECURE UNIFORMITY IN SIZE OF BRICKS.

A conference was recently held in London between representatives of the Royal Institute of British Architects, the Institution of Civil Engineers, and the Institute of Clayworkers to consider the question of standardizing the size of bricks. There was placed before the conference the following standard suggested by a joint committee of the R.I.B.A. and the Institution of Civil Engineers :

1. The length of the brick should be double the width plus the thickness of one vertical joint.
2. Brickwork should measure four courses of bricks and four joints to a foot.

Joints should be 1-4 in. thick and an extra 1-16in., making 5-16in. for the bed joints to cover irregularities in the bricks ; this gives a standard length of 9 1-4in. centre to centre of joints.

The bricks to be measured in the following manner :—

Eight stretchers laid square end and splay end in contact frog upwards, in a straight line to measure 72 in.

Eight headers laid side by side, frog upwards, in a straight line to measure 35in.

Eight bricks laid, the first brick frog downwards, and then alternately frog to frog and back to back, to measure 21 1-2 in.

This is to apply to all classes of walling bricks, both machine and hand-made, and facing bricks."

Representatives of a number of brick manufacturing firms gade expression to their views, and referred to the difficulty of producing bricks to a standard size—especially as regards length—owing to shrinkage in the kiln. One manufacturer pointed out that to burn the darkest red color it was necessary, or usual, to burn these bricks stood on end, and consequently the weight of the bricks above, and the heat of the fire below, made these oftentimes shrink nearly half an inch in length.

On the other hand the Chairman of the Kent and Essex Brickmakers' Association said the brickmakers were quite capable of making any size or any shaped brick that engineers or architects might require, if architects or engineers would pay the price for it ; but the fact was that the engineer required the very best brick he could get, and he wanted to give the very lowest price for it. Another speaker put this fact in a different way by saying that if a rule were made that bricks were to be a certain length, with no allowance for uncertain contraction, they would have to be sorted, and hence become more expensive.

The conference resulted in the appointment of a committee representing all parties concerned, to consider the desirability of making the size of bricks uniform throughout Great Britain.

In this connection the following table of normal brick dimensions in various countries is of interest :—

	Length ins.		Width ins.		Thickness ins.
United States	8	x	3¾	x	2½
Germany (normal)	9⅞	x	4¾	x	2 1/16
" (north-west)	8½	x	4⅛	x	2¼
" (Bavaria)	11½	x	5½	x	2⅜
Austria	11½	x	5½	x	2 1/16
Italy	9	x	4 1/16	x	2 to 2¾
France	8⅝	x	4¼	x	2⅜
Belgium (Brussels)	8	x	3¾	x	2⅜
" (Liege)	9	x	4⅜	x	2½
" (Boom)	7⅛	x	3⅜	x	2
Switzerland	9⅞	x	4¾	x	2⅜
Russia	10⅜	x	4⅞	x	2 11/16
Holland	8½	x	4⅛	x	2⅛

Wood Fiber Plaster

Patented in Canada Dec. 6th, 1899.

POINTS OF SUPERIORITY—Deadens Sound, Non-conductor of Heat and Cold, Sets on the Wall in two hours.

Is a Substitute for Common Plaster

It is offered to the public as unquestionably the best plaster ever made, and will, as it becomes known, supersede all other forms of plaster.

Manufactured by

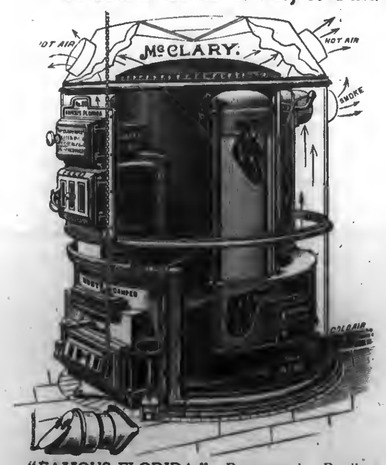
W. A. Bradshaw

109 Front Street East, Toronto.

Telephone Main 1552.

THREE FURNACES All Fully Guaranteed. The Result of Fifty Years Making Them

We make a Furnace for every condition of heating, a size to suit every house—whether large or small



"FAMOUS FLORIDA." Burns coal. Really a large base-burner, and as economical as one. Has direct and indirect drafts.

"SUNSHINE FURNACES" Made in Three Sizes

Burns Coal, Coke or Wood, and gives perfect satisfaction with either.

"FAMOUS MAGNET." Burns wood. Extra heavy fire box and linings. Direct and indirect drafts.

THE WINDSOR PLASTER CO.

The works of this company, situated at Windsor, Nova Scotia, are from two to five stories in height and cover a floor area of 43,000 square feet. In 1893 the company commenced the manufacture of calcined land plaster, and the year following began the production of English Selenite Cement for plastering walls and ceilings. This material has been favorably received and largely used by architects and builders throughout the Dominion.

THE RELATION OF WALL PAPER TO DISEASE.

Some of the Master Painters' Associations of the United States are calling the attention of city councils and local Boards of Health, to the necessity for a regulation forbidding the hanging of wall paper without previously removing the old paper from the wall. Many cases of infectious and other diseases are said to be traceable to the practice of covering up old wall paper with new. There is a regulation in New York which prevents the re-papering without first cleaning the walls, but it applies only to tenement houses. It is no doubt particularly applicable to houses of this character, and if so, would seem to be also necessary in the interests of the public health, for buildings of all kinds where paper is employed as a wall covering. Not only should the old paper be removed from the walls in every instance before new paper is hung, but walls should always be washed with carbolic acid or other disinfectant.

If you are looking for a high grade Finish for Floors

Granitine Floor Finish.

Is unsurpassed in Durability and Beauty of Finish for Natural Wood and Parquette Floors, Linoleums, Oil Cloth, Cork Matting, &c.

Its transparency reveals the grain of the wood, and its preserving qualities increase the life of the floor.

Its sanitary properties are highly commended, as it closes thoroughly the pores of the wood against disease germs, and permits the floor to be kept thoroughly clean.

It is easier applied, more durable, makes better finish than wax preparations, and is free from all unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks; nor does soap, mud or water destroy its fine appearance.

Manufactured only by

The Imperial Varnish & Color Co., Limited

TORONTO, ONTARIO, CANADA.

MANUFACTURES AND MATERIALS

WOOD FIBRE PLASTER.

Mr. W. A. Bradshaw has recently established a factory at No. 109 Front street east, Toronto, for the manufacture of wood fibre plaster, a patent compound, one of the most important ingredients of which is wood fibre, which gives flexibility, toughness, lightness and strength. The advantages claimed for this new plastering material are: that it it quick-setting, proof against disintegration by frost or heat, is a non-conductor, withstands effect of vibration and can be decorated in any manner. For further particulars the reader is referred to the announcement of the manufacturer in the advertisement pages of this number. Twenty tons of this material are being used to plaster the large summer hotel now in course of construction on Lake Rosseau, Muskoka.

The Sackville Freestone Company, Limited, was recently incorporated at Sackville, N.B., with a capital stock of $24,000. The members of the company are Fred. P. Thompson, Fredericton; Andrew M. Bell, Halifax; John W. Lowe, Amelsford; Charles Pickard, Sackville, and P. J. Mooney, St. John.

Protecting iron has been simplified by a Frenchman. The process consists in treating the casting with dilute hydrochloric acid, which dissolves a little of the metal and leaves a veneering of graphite on the iron. The article is then washed in a receiver with hot or cold water, so as to remove the chloride of lime that has been formed.

The Canada Foundry Company have purchased the business of the Dominion Ornamental Iron Company, Toronto, and will conduct it as a Department of their extensive new works now in course of construction at the corner of Davenport road and Mackenzie avenue. It is understood that Mr. Joseph Lea, late manager of the Dominion Ornamental Iron Company, will be in charge of this branch of the Canada Foundry Company's business.

CATALOGUE FOR THE ASKING

AMERICAN SUBSTITUTE FOR SAND-PAPER.

Steel wool, introduced five or six years ago, is a machine-produced material that is used as a substitute for sandpaper. It is composed of sharp-edged threads of steel, which curl up together like wool, or somewhat as the wood fibres of the familiar material known as excelsior curl up together, though the steel wool is very much finer, the finest of it being not much coarser than the coarsest of natural wools. The steel wool is put up in packages containing 1 lb. each. These are something like rolls of cotton batting, but smaller; 1lb. of steel wool, loosely packed, making, rolled in paper and open at the ends, a package perhaps 15in. long and 2in. or 3in. in diameter.

Made in various degrees of coarseness, steel wool is put to a variety of uses, the finer wools for polishing wood and metal and the coarser for rubbing down paint and varnish. It is often used on special parts of work. While, for example, on the flat surface of a door a man would use sandpaper with a block back for it, for the mouldings he would use steel wool, which fits into the crevices and conforms into irregular shapes. Such work can be done with steel wool far more readily and quickly than with sandpaper and it is used with this advantage on irregular and small surfaces and on carved work.

Besides the steel wool there is coarser material of the same kind called steel shavings, which is put to various uses; as in taking off old paint or varnish, and in polishing wood before painting, and it is used on bowling alleys and on floors for smoothing and cleaning them. Sandpaper clogs in use; steel wool breaks down. The wool is commonly used with gloves to keep the ends from sticking into the fingers.—Woodworker.

Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.

LEGAL.

Mr. Thos. Mowbray, of Toronto, one of the unsuccessful competitors in the competition instituted by the Dominion Government for designs for statues of Queen Victoria and the late Hon. Alexander Mackenzie, has entered an action for damages against the Minister of Public Works on the ground that the model which he sent to Ottawa, was seriously damaged as the result of being carelessly and improperly packed by the Government officials.

Brennan vs. Harding & Leathorne.—In this action tried before a jury at London, Ont., on April 12th last, B. was employed by a firm of contractors, and while working in a ditch, at a distance of about ten feet below the surface, was injured by a cave-in. He claimed that the accident was caused by lack of proper "shoring," and that he was injured for life, and sued the contractors for $5,000 damages. The contractors asserted that every precaution had been taken, and that the accident was occasioned by what could not have been foreseen. During cross examination B. admitted that the contractors had treated him well—that they had paid $140 for doctor's bills and hospital charges, and had insisted upon his returning to the hospital after he had left it. B. also admitted that he had gone out of the hospital when the doctor had advised him not to do so, and that he had taken a few drinks, which the doctor told him had delayed his recovery. The jury gave a verdict in favor of the contractors, and the action was dismissed.

Harris vs. Martin.—In this case argued recently before Chief Justice Falconbridge, in the Divisional Court at Toronto, judgment was given on appeal by plaintiff from judgment of County Court of Perth dismissing action for injunction to compel removal by defendant of a gable on his house, overhanging plaintiff's land, and to restrain defendant from permitting water, ice and snow to blow off the roof thereof upon plaintiff's land. The plaintiff and defendant were purchasers of adjoining properties from a common grantor, the plaintiff having purchased in 1891, and the defendant in 1893. The judge below found that the plaintiff's purchase covered all the land up to the wall of the house occupied by the defendant, including the land under the overhanging gable, and that the law, as laid down in Wheeldon vs. Burrows, 12 Ch. D. 31, preventing any implication arising in favor of a reservation by plaintiff's grantor of any easement in derogation of the grant, was subject to exception in the case of easements of necessity, and that the easements of maintaining the gable and allowing the water, ice and snow to be deposited from the roof upon plaintiff's land, were easements of necessity within this exception. Held, that under the circumstances such as here existed, the rights of the grantee are to be found in the terms of his conveyance, subject to an exception in cases of necessity, of so urgent a nature that it would not be possible to conceive the intention of the parties to the contract to be complete without admitting the implication. Assuming, as the judge of the County Court found, and as the plaintiff does not now dispute, that Cornelia Armstrong conveyed to him all that part of lot 17 lying to the east of the brick wall, and there is no necessity compelling the court to imply an intention on her part to reserve to herself the right, inconsistent as it is with the terms of the grant, to maintain a roof overhanging the land conveyed, or a right to cast water and snow upon it. The overhanging roof is not an essential or vital part even of the small building of which it forms part, and it may be removed and other means adopted of disposing of the rain and snowfall without any great difficulty—certainly without so much difficulty as the court would have in assuming a grant from the plaintiff of the rights claimed by the defendant. Judgment below varied by dismissing the claim of the plaintiff as to the portion of lot 17 lying to the west of the line of the east face of the brick wall of the defendant's house, produced in both directions, and by restraining the defendant from trespassing upon the land of the plaintiff being all that portion of lot 17, lying to the east of the said line by maintaining any structure overhanging it, or by shedding snow or water upon it, or otherwise. Plaintiff to have against the defendant the costs of the action, excepting in so far as the costs of the issue with regard to the two and a half feet are concerned, which costs are to be taxed to the defendant; the plaintiff also to have the costs of the appeal.

(LIMITED)

Hamilton, Ont. - Montreal, Que.

NOTES.

Compoboard is made of wooden slats 4 feet long and 1 inch wide, joined in an endless webb, so that the 4 feet length of the slat forms the width of the complete board. Therefore in a long board, say 4 feet x 9 feet, the end-grain of the wood s on the longer edge; in small pieces the end-grain edge is readily detected by the fact that it shows the joining of the slats inch by inch. The faint lines at the top show how the slats run from end-grain edge to end-grain edge. Always join the board on the end-grain edge. Let the joint be as tight as possible. It will never alter by shrinking or swelling, and when suitably stopped can be painted, papered, or distempered. The board is made in no less than six qualities, and they range from 7-32 of an inch to ⅜ of an inch.

BUILDING CONDITIONS.

There is much activity in building throughout Canada this season. In Winnipeg, the value of new buildings according to the permits issued, nearly doubles last year's record. In Toronto all the architects appear to be busily engaged. Domestic work is calling for a large share of attention. Some important and interesting buildings of this class are in progress, while less costly dwellings are springing up on every hand. The majority are being built as homes by the owners. There is also a considerable amount of speculative building of the better class. It is gratifying to note that the designs for most of this work were prepared by local architects, and in consequence good taste prevails to a much larger extent than in the past, when the builder undertook to be his own architect. The high cost of lumber has undoubtedly retarded building enterprise, and the strikes of workmen in Ottawa and elsewhere are hindering operations and blocking new undertakings.

RUSSIAN PAVILION AT THE GLASGOW EXHIBITION.

RELATIVE VALUE OF FIRE RESISTING MATERIALS.

Some valuable data concerning the fire resisting properties of various materials and methods of construction have been made available by a series of tests conducted in connection with the recent Building Trades Exhibition in London. These tests related to floors, partitions, doors, both of wood and iron, and protective coverings to open spaces. As regards flooring, it was found that by filling up with plaster to the extent of 1 in. the soffit of an ordinary floor having deal joists, a floor was rendered fire-resisting for 45 min. When slag wool was similarly used it stood the test of one hour's duration. A floor made of simple baulks of timber laid side by side, the thickness of the baulks being 9 in., stood an 80 min. test, with a gradual temperature up to 2,000 degrees Fahr. The result was that the under surface of the wood beams was charred to the average depth of about 2in., but beyond this no damage was done. A floor protected by 5in. of concrete was destroyed in 54 min. A simple iron and concrete floor was next tested. After an hour and a half the bulk of the concrete collapsed owing to the deflection of the steel plates. A floor constructed of iron and concrete, in which all the ironwork was embedded, stood a very severe test. The fire did not pass through it, and wood strips imbedded in the upper surface of the concrete were uninjured. With regard to partitions, one formed of terra cotta, wired lathing, covered with plaster of paris, stood a very severe test. It was found that doors of oak and teak stood the most severe test, and with regard to windows it was found that blinds of asbestos cloth were a great protection from the spread of fire.

FIRE-PROOF GLASS WINDOWS

THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

A $10,000 Arch.

The Canadian tour of the Duke and Duchess of Cornwall and York will be a great occasion, and it is suitable that we should acclaim it with a lavish display of street decoration; but we cannot help feeling that there is a touch of extravagance about the $10,000 arch which the Manufacturers' Association of Toronto propose to erect as a temporary decoration. It is proposed to offer three prizes, handsome prizes too, for suitable designs for the purpose. The test of excellence in this case is certainly the greatest display for the least money; and it would be a good way of going about the matter, not to invite the outlay of this or any definite sum; but, having secured the location, to offer the prizes for its suitable decoration. There is a limit to reasonableness in temporary decoration, and good taste is within this limit, so that the designer who hits off the pleasing thing will very likely not be the most lavish. In other words, it ought to be understood that though the Manufacturers have voted enough money to cover all needs, the competition is not for the purpose of showing how to spend it all, but in order to establish sufficiency, "an elegant sufficiency." In order to encourage designers to incur the risk of self-restraint (which is notoriously bad policy in a competition) there should be an additional prize offered to the winner, in the form of a bonus, a percentage on the amount saved, given by the Museum Committee, who would of course get the balance. It is for just such a $10,000 gift as this that the Museum project has been waiting. If it were not for that, one would think of the Manufacturers' action only to admire their wealth and liberality. But the readiness with which the glory of the city is forwarded, in a matter of a two days' display, and the difficulty experienced in getting subscriptions for a project which is acknowledged to be necessary for her permanent advantage is remarkable; and one cannot help regretting that it is thought necessary to spend so large a sum upon the temporary erection, when half of it might perhaps do, and the other half go to help on the subscription for the permanent structure.

Toronto City Building By-laws.

For some years past a request for a copy of the building by-laws of Toronto has been met by a statement that there are none because the by-laws are being revised. The by-laws appear to have never existed, except in a fragmentary form, and if this revision, that has been under way so long, is ever completed, the result should be published in the form of a volume containing all the laws and directions which have to be observed in building operations. But they should, above all things, be published soon, or what was revised when the revision began will be out of date. Building operations are at present labouring under the difficulty of laws that are behind the time. Officials, whether as men they know anything or not, as officials know nothing but the law. The

law takes no cognizance of the fact that cement in the mortar of a brick wall is as good as a half brick in thickness; therefore officials are not open to reason upon this point. The law says that a steel beam over a small shop front is fire resisting. Experience points to the superiority of a wooden bressummer; but officials are not open to the argument from experience. The law requires the house trap to be set at such a distance from the house that to connect the weeping tile system beyond it adds extravagantly to the cost of drainage. The law appears to contemplate connecting the weeping tiles behind the house trap in such a way that if the trap is stopped, the whole system of surface drainage must be filled with the backed-up sewage before it can climb high enough to appear in the laundry tubs. It is strange that the plumbing by-law, which is the most modern part of the building law, should contemplate this; but it is stranger still that the officials should want to hold to the law. As a matter of fact the greatest danger is to the authority of the law and the officials; for, when architects know that they are right and the law is wrong, they simply ignore its interference. This state of affairs is unwholesome, and it is time we had a law which can command and enforce respect.

A Regular Size for Bricks.

Architects are complaining of the trouble caused by variations in the size of bricks. It is impossible to figure plans with certainty until the bricks are on the ground. It is not that there is not a standard size, or that the bricks are not made according to it; but simply that the makers use wooden moulds, and do not renew them often enough. A full sized brick is therefore seldom seen, and perhaps the greatest trouble of all is a lot of bricks from a new mould; for calculations based on a slim specimen are more impossible, when full sized bricks are delivered, than a full sized calculation would be for small sized bricks. It is more easy to gain in brick laying than to work down. As far as appearance is concerned, it is hard to err on the side of a fat joint in ordinary brickwork; and, up to likely limits of joint thickness in ordinary work, construction is improved by the necessity which arises for good beds of mortar. But to be obliged to batter down the bricks to meet the figures is something to which both bricklayer and architect object. There is nothing to be done, when a brickmaker has renewed his moulds, and unexpectedly delivers bricks up to the standard, but to re-figure the drawings; and that probably at the height of the season, when there is already too much drawing to do. The remedy is the adoption of a standard size, recognized as part of the building contract; so that brickmakers can only withhold the renewal of their moulds at a risk which would make such economy of doubtful advantage.

Roof Gardens

It seems a little odd that there has not yet been a serious attempt to make use of flat roofs for something more than the purpose of drying clothes. There would be nothing new in having upon one of these roofs, a garden with shrubs and even trees growing in it. The hanging gardens of Babylon may afford us little encouragement, knowing the probable bulk of walling and vault on which they rested; but in later days and nearer home there are examples. The Ducal Palace of Mantua has a dining hall, in the upper or principal storey, with windows opening down to the floor, and looking upon a garden at the same level in which there is a tree between twenty and thirty feet high. This green outlook must have been a beautiful addition to the dining hall in the days when the palace was inhabited. The garden is carried by the vaulting over a wine cellar on the ground floor; not more substantial probably, or more impervious to moisture than the flagged surface of the roof on the Bowling Green Building in New York. One might venture to predict that a restaurant in the comparatively fresh air of this roof, even if it went no further in gardening than orange trees in tubs, would be a formidable rival, for at least six months of the year, to the prosperous affair across the road, into which one decends two levels below the street. One objection to pioneering in this direction is that for a pioneer, surrounded by unimproved neighbours, the surroundings are apt to be squalid. But there are buildings in a favourable neighbourhood, and in a favourable state of isolation, in the case of which such an experiment would be worth trying.

The S.P.S. Building

Prof. Galbraith and his assistants have returned from their tours in search of information to apply to the new building for the School of Practical Science, and yet nothing has been heard from the government as to the appointment of an architect or the arrangement of a competition for this building. The inference is that the plans, upon which the provincial architect was understood to be working before he went on tour with Prof. Galbraith, are the plans of the school. There are two things to be said about this. The first is that the plans which were under way before the tour for information came off, cannot be profited in any fundamental way by the tour. The second is that this is not work that can be so well done in the Provincial Architect's office as out of it. The best thing that can be done with the information the Provincial Architect has gained by his tour is to put it in form for the guidance of the participants in a competition. The sooner the Minister of Public Works understands that in forcing this work through the Public Works Department, he is mishandling the responsibilities of his office, the better. If he does not realize it now he will realize it later when the building is in a position for the public, and the students who will use it, to judge whether the best has been done that could be done. The Minister of Public Works of course knows no more about architecture than he does about ballooning. He is not expected to know anything about architecture; but he is expected to know that the ferment there has been about this building, at the mere suggestion that it should be done in the Public Works' Department, is not for nothing. It is not only architects, but the Guild of Civic Art (moved by persons who are neither artists nor architects) who have taken up the matter. The government have had a fair chance to take up this matter in a large way. The deputation of students was conclusive to show that this province is in competition with the United States to keep her students. It was no case for timidity, and the government seem to have realized that. They had better realize now that it is no case for small dealing in any respect. In the interest of a reputation, which in building matters requires careful handling, let them take steps to get this building done with one thought only—to get the best that is to be got.

Factories Outside of Cities

To any one watching the six o'clock rush out of a large city, the question must occur, is it necessary for all these people to do their work in the same part of the city? Why should all these factory operatives live on the outskirts of the city; coming in every morning in haste, only to go out again in haste in the evening; when their work could be done as well in the suburb where they live? Some factories are located on the railways on the edge of the city and there seems no reason why there should not be a district in each city (preferably eastward in this country, where the prevailing winds are westerly) in which facilities provided by railway concessions would invite the establishment of factories. With the worst disposition of space, such an arrangement would be more convenient than the present manner of concentrating every kind of work in the city. If properly managed, there would be opportunity offered for the growth of little factory settlements in which, after the manner of Messrs. Lever Bros.' village of Sunlight, the labourer would be near his toil and need waste no time in going to and from it. It is not work that is the labourer's curse, but want of leisure; and that he should waste what little time he has, that he can call his own, in going to and from home in the crowded street cars—a journey that will increase in distance continually—is an evil which is not necessary; and to take steps to get over this state of affairs is to do the best thing that can be done to ameliorate the labourer's lot. A couple of hours a day added to their time will with many men be devoted to pursuits producing continual self improvement. Much can result in a few years from a little done each day. There is at least opportunity for the advantage of positive recreation, and the profit of a little gardening. Where nearness to the centre is not all important, the expansion of a city may be considerable, and land not too valuable for a little to go with a workman's cottage.

To Straighten Niagara.

Mr. Joseph I. Keefer has, according to the Buffalo Courier, submitted to the Niagara Falls Commission a plan to cut away a portion of Goat island, build an abutment and "connect the American and Canadian Falls in one grand torrent of water." "My idea," says Mr. Keefer, "is to build a great giant wall or abutment, with a stone top or coping, that cannot be washed away, and let the water from both sides of the island gracefully glide over the dam or stone esplanade, thus making one continuous stream of pure white water from the jut of one shore to the jut of the other." Mr. Keefer explains how this great idea came to him. "I was standing over on the Canadian side where the old British Museum used to be, and, looking across, the thought struck me how much prettier the falls would be if they were not broken by Goat Island." It would be difficult to take this proposition seriously, if it were not that the Commissioners are reported to have already done so. The Commissioners are reported to have "seemed much taken with the idea, and wondered why no one had ever thought of it before." And they are going to have their engineer "figure on it," to ascertain the probable cost. It is a serious fact that public culture is far behind public wealth in the United States, and an atrocity, such as is here contemplated, is always within the possibilities. It would be difficult to persuade a jury of Mr. Keefer's peers that the intrusion of Goat Island is one of the distinguishing beauties of Niagara. His scheme might be attacked on the ground that the unfortunate break in the middle of the Canadian Fall will destroy the perfection of his line, and that the green water in the centre of the horseshoe will forever disturb the prettiness of the "continuous stream of pure white water from the jut of one shore to the jut of the other." Against this petty objection he can urge, as he does, that "the people ought to be interested in this improvement, for it will make a new falls at Niagara. It will stimulate the interest of those who have never seen the falls before, while those who have seen them will be anxious to come again to see what has been done to preserve and improve one of the greatest American wonders." In all this Mr. Keefer shows sound business instinct, and (always supposing that the state of New York can have any reasonable motive for organizing a one lively season of this kind at the Falls) he might add the rush of people both on this continent and from Europe who realize that it is their last chance to see Niagara Falls as the world has hitherto admired it.

BY THE WAY.

THE London Telegraph tells of a squeamish architect who in travelling from Dieppe to Paris, refused to surrender his railway ticket to the guard because the latter's hands were not immaculate, and he declined at the architect's suggestion to cover them with gloves. The case found its way into court, and the architect manfully defended his attitude, but was fined £4.

× × ×

IN Berlin there has been founded an institution exclusively reserved for young women desirous of learning the art of painting—not pictures—but buildings. The course of instruction in this school is complete. Not only do the young women learn to handle the brush, mix the colours, but a professor of gymnastics comes twice a day to give instruction in climbing ladders and maintaining one's equilibrium on planks and scaffoldings.

× × ×

Mr. Illsley, a member of the firm who have the contract for the erection of the large hotel in Toronto, is given as authority for the statement that the taking down of the old buildings on the site was the speediest bit of work he ever witnessed, either in Chicago or elsewhere. This testimony to Canadian skill and energy, from a contractor of long experience in the United States, where the speediest methods are sought to be employed, is very acceptable, as showing that our contractors are up-to-date.

× × ×

THERE is no need for an alien labor law in Budapest Public Sentiment is sufficient to keep out foreigners. In consequence of negotiations having been opened with a firm in Vienna to construct a new national theatre in that town, the majority of the leading actors and actresses have pledged themselves not to accept an engagement in a theatre on which any Austrian architect, builder, decorator, painter, mason, or any kind of labourer had been employed, and a theatre built by the hated foreigners will be rigidly boycotted by nine-tenths of the population of Budapest.

× × ×

WITH the incoming of the twentieth century, comes the announcement that the concentrated heat of the

sun's rays has been applied to the burning of bricks. The thing is so simple, says the British. Claymaker. Take a mirror and throw a spot of sunlight on a green brick. It will warm it, say, 15 degrees. Take 1,600 mirrors and throw 1,600 spots of sunlight on a brick. Result, it will warm it 15x1,600=24,000 degrees. What could be simpler, and here we have ten times the temperature necessary to burn a firebrick, without any expenditure but a few bits of looking-glass, which won't wear out!

× × ×

I observe that an order has been given to a Montreal firm to decorate and refurnish the residence of the Governor General at Ottawa in view of the approaching visit of the Duke of York. Any money which may be spent in re-habilitating Rideau Hall, or at least the older portion of the building, will be to a large extent thrown away, as the building appears to be almost in a tumble-down condition. Canadians have no reason to feel proud, but rather ashamed, of the executive residence at Ottawa, which does not even compare favorably with the residence provided for the Lieutenant Governor of Ontario. If the country is to continue to have a Governor General and to pay him a large salary, our self respect demands that we shall provide him with a residence in keeping with his position.

× × ×

No better indication is required of the change that has taken place within the last two or three years in building conditions in Toronto than the fact that architects are now said to be complaining of the difficulty of securing satisfactory tenders from contractors. The latter are so fully occupied that they are not disposed to go to much trouble to secure the less desirable class of contracts. Only a few years ago the situation was very different. There were then too few contracts going to keep the contractors even moderately well employed, and as a result the competition was far too keen to permit of fair profits being obtained. Another indication of the activity now prevailing is an advertisement in the daily press from the secretary of the Builders' Exchange for skilled mechanics.

× × ×

The desirability of establishing one or more centra squares in Toronto is not open to question. It is one of the greatest needs of the city. To my way of thinking it is more essential than the clock and bells recently installed in the hall tower at a cost of about $30,000. If the city could not afford both, the money should have gone towards a lease of the land opposite the new municipal buildings, for the purpose of a public square. The opportunity of securing the land may at any time pass, hence the wisdom of prompt action. While on this subject, I would like to make the further suggestion that land for a public square should be purchased in the part formerly known as St. John's ward, in which the population is the poorest and most congested. As a means of improving the physical and moral status of the district, it should prove a profitable investment.

× × ×

What is known as the Art Renean, which probably had its origin in France, is the dominating characteristic of decorative work in Europe to-day. Its chief feature is perhaps following lines. In wall papers, the new style, which combines grace in design with skilful color combinations, has displaced the gaudy patterns which were lately so much in vogue and which had so little in the way of true artistic merit. Some excellent examples of decoration in the new style—the work of Scotch and English firms—are to be seen at the Glasgow Exhibition. The chief feature of this Exhibition, however, is said to be the magnificent colletion of paintings in the new permanent Art gallery. The temporary Exhibition buildings, are heavy in appearance by comparison with those of the Pan-American Exhibition, and to a Canadian their effect is less pleasing, but considering the eminently practical and substantial character of the city and people, it was to be expected that these buildings would in some measure reflect their surroundings.

× × ×

In a recent conversation with Mr. W. H. Elliott, of Toronto, who has lately returned from a three months European tour, I gathered some impressions concerning matters artistic abroad. Regarding Italy, the principal cities of which he visited, Mr. Elliott states that the land which was once the home of the greatest artists, would now be devoid of artistic interest but for the works of the old masters. Strange, is it not, that there are no great Italian artists of the present day, and Italy is making but feeble and unsuccessful attempts to keep pace with modern progress in art, so far at least as the fine arts are concerned? In applied art she is more successful, as witness her exhibit at the Paris Exhibition last year. The character of present day Italian Sculpture, of which the production is considerable, bears witness that the genius which inspired the Italian artists of a former period, no longer exists. The conception and spirit of the true artist are wanting. The work of the present day is mechanichal, commonplace and without interest.

× × ×

A storm of indignation was recently aroused in Hull by a new building by-law, which, with the view of preventing the recurrence of the disaster of last year, prohibits the erection of wooden dwellings. Several hundred citizens waited on the city council recently, demanded that the by-law be repealed, and hissed the mayor and aldermen. The mayor appointed a time to receive a deputation, representing the citizens, and to hear and consider their views. There can be no doubt that the restrictions imposed by the by-law will be burdensome upon the many owners of cheap properties, but that should not be allowed to stand in the way of enactments which are necessary to the preservation of property of vastly greater value. The proximity of Hull to the Dominion capital should be considered. The council of Ottawa is probably powerless to protect itself against danger from an adjoining municipality, but in the event of such adjoining municipality neglecting or refusing to adopt regulations for its own protection and that of its neighbor, the provincial or federal government might not unreasonably be asked to pass special legislation dealing with the case. If the property owners of Hull cannot afford to put up buildings other than those of the most hazardous character, they should be prepared for the sake of general welfare to live outside city limits, which, in these days of rapid electric transit, is no hardship, but on the contrary, is by many city people counted a privilege.

MONTREAL PLUMBING BY-LAW.

Following are the full provisions of By-Law No. 215, of the City of Montreal, concerning plumbing and the drainage and ventilation of buildings, as adopted by the Council of that city on June 12th last:—

Sect. 1.—No person, firm or corporation shall, after the first of September, 1901, engage in or work at the business of plumbing, either as a master or employing plumber, unless such person, firm or corporation, has received a license or certificate therefor in accordance with the provisions of this By-law relating to these as hereinafter contained.

(1) The word "Master Plumber," as used in these regulations, shall be deemed to mean one who employs practical plumbers or journeymen plumbers, and who keeps a shop or place of business for which he is held to pay a business tax to the city.

(2) Any person engaged in or working at the business of plumbing, prior to the passing of this By-law, and desiring to engage in or work at said business, either as a master or employing plumber in the City of Montreal, shall on or before the first of September, 1901, apply to the Board of Examiners hereinafter provided for, to be examined as to his qualifications for such business.

(3) In case of a firm or corporation, the examining and licensing of and granting a certificate to any one member of the firm or the manager of the corporation, shall satisfy the requirements of this By-law.

(4) There shall be a Board of Examiners of plumbers, consisting of the Building Inspector or his assistant, the Sanitary Engineer (who shall be a member of the Board ex-officio), and a licensed master plumber of at least ten years practical experience, to be appointed by the City Council, for the term of two years at a time. Said third member to receive as compensation for his services a sum not exceeding five dollars a day of actual service.

(5) The said Board of Examiners shall then appoint a chairman, and designate the time and place for the examination of all applicants desiring to engage in the business of plumbing within the City of Montreal. Said Board shall examine said applicants as to their practical knowledge of plumbing, house drainage, and plumbing ventilation, and shall submit the applicant to some form of practical tests, and if satisfied of the competency of the applicant, shall so certify and issue a license, authorizing him to engage in the business of plumbing in Montreal, either as a master or employing plumber.

(6) The fee for a license shall be five dollars for a master or employing plumber, and said license shall be renewed yearly, on the payment of one dollar.

PLUMBING, DRAINAGE AND VENTILATION OF BUILDINGS.

Sect. 2.—Every master plumber shall be required to register his name and place of business at the office of the Board of Health, and to give notice at the said office in case of the removal of his place of business.

(1). An official list of such plumbers, recognized by the Board of Health, shall be posted, once a year during the month of May, and copies thereof shall be furnished to those who may ask for the same.

(2). It shall be unlawful for any person to carry on the trade of plumbing in the City of Montreal, unless licensed or registered as above.

(3). Every licensed master plumber shall be held responsible for all the acts of his agents or employees, and any licensed plumber who neglects or refuses to comply with the provisions of this By-law, may have his license suspended or cancelled by the Board of Health, in which case he shall be barred from obtaining a permit to do any work during such length of time as the said Board may deem proper.

Sect. 3.—All plumbing and house drainage, and ventilation in the City, shall be made and constructed in accordance with the following rules, which shall be binding on all parties concerned.

(1). No drains shall be made, or plumbing work done in any building, until a permit to do so has been obtained from the Sanitary Engineer.

(2). No alteration of drains or plumbing work in any building affecting its sanitary condition shall be undertaken before giving notice to the Sanitary Engineer. Forms of application, and specification for the drains and plumbing work of a new building and for alteration of the same in old buildings, will be supplied by the Health Department.

(3). Pipes, drains and plumbing work shall not be covered or concealed from view, until approved by the Inspector of the Board of Health, who shall examine the same within two legal working days, after notice that they are ready for inspection.

(4). The material used shall be of good quality and free from defects, and the work shall be executed in a thorough and workmanlike manner.

Sect. 4.—The arrangement of the soil, waste and ventilation pipes shall be as perpendicular and direct as possible.

(1). The soil, drain, waste and drain ventilation pipes shall be exposed to view, ready for inspection and for convenience in repairing.

(2). When necessarily placed within partitions or recesses of walls, soil, drain, waste or ventilation pipes shall be covered with woodwork, so fastened with hinges or round headed screws, as to be readily uncovered.

Sect. 5.—Every house or building shall be separately and independently connected with the street sewer, in front of such house or building, or with such other sewer as shall be designated by the Board of Health.

Sect. 6.—Interior house drains when above ground shall be of extra heavy cast iron pipe. When laid under ground, drains shall be of cast iron or vitrified clay pipe, and shall have a fall of at least 1-4 inch to the foot. Where water-closets discharge into them, the pipes shall be at least four inches and not more than six inches in diameter and be laid in a straight line if possible. All changes in direction shall be made with curved pipes when of cast iron, and with Y pipes when of vitrified clay; and at least one clean-out length shall be provided at each change of direction.

In all cases of soft ground, vitrified clay pipes must be laid upon at least four inches of concrete.

Sect. 7.—No bricks, sheet metal, earthenware, or chimney flue, shall be used as a sewer ventilator, or to ventilate any trap, drain, soil or waste pipe.

Sect. 8.—Soil pipes shall be of cast iron of the weights specified in section 15 and shall extend at least 2 feet above the highest part of the roof, or coping, undiminished in size, and in no case shall they be less than 4 inches in diameter; where the soil ventilating pipes come within 15 feet of any windows, open lauvres, or other openings, they muse be carried up 5 feet above top of such window or opening.

Soil, waste and vent pipes, in an extension, shall be carried above the roof of the main building when they are closer than 20 feet to the windows of the main building.

Sect. 9.—All traps shall be adequately protected from syphonage or air pressore, by vent pipes of a size not less than one and a half inch in diameter vented by the open air through the roof, unless where antisyphon traps or other approved devices are used.

Sect. 10.—Joints of sewers and soil pipes shall be gas and water tight.

Sect. 11.—When stacks of pipe are required for sinks only, they shall be carried through the roof and be not less than 2 inches for 4 sinks or 3 inches for over that number; but the portion above the roof, in all cases, must be 1 inch greater diameter than that below the roof.

Sect. 12.—When lead pipes are used to connect fixtures with vertical soil or waste pipes, or to connect traps with vertical vent pipes, they shall not be lighter than 6 lbs. sheet lead to the square foot. All such pipes shall be properly supported to prevent sagging.

Sect. 13.—There shall be no traps in connection with vertical soil or waste pipes.

Sect. 14.—All pipes shall be sound and free from holes or cracks.

Sect. 15.—The following weights per lineal foot, for cast iron and lead pipes, are the minimum weights :

IRON PIPES.

(Interior measurement)

For Plumbing Work.

2 inch 4 pounds per lineal foot.
3 inch 6 1-2 pounds per lineal foot.
4 inch 9 pounds per lineal foot.
5 inch 12 1-2 pounds per lineal foot.
6 inch 17 pounds per lineal foot.

For Drain Work.

4 inch 13 1-2 pounds per lineal foot.
5 inch 17 pounds per lineal foot.
6 inch 20 pounds per lineal foot.

Lead Pipes.

1 1-4 inch 1 1-2 pound per lineal foot.
1 1-2 inch 2 pounds per lineal foot.
2 inch 2 1-2 pounds per lineal foot.
2 1-2 inch 4 1-2 pounds per lineal foot.
3 inch 5 1-2 pounds per lineal foot.
4 inch 7 pounds per lineal foot.

For Waste Sink Pipes.

2 inch 10 pounds per lineal foot.
3 inch 15 pounds per lineal foot.

(1). Iron pipes shall have their weight stamped upon them.

(2). Leadwaste pipes, bends or cess-pools, shall be equal to not less than 6 lbs. per square foot of sheet lead.

(3). The fittings used in connection with such pipes shall correspond with them in weight and quality.

Sect. 16.—Plumbing work shall not be used unless the same has first been tested in the presence of the Sanitary Inspector, or his representative, with the water test, or if that is not practicable, with the peppermint, smoke or other reliable test, and if said test is satisfactory, he shall issue a certificate to that effect.

(1). The Water Department, for the purpose of such test, shall temporarily turn on the water, and shall only permanently turn on the water when the certificate of the Inspector is produced.

(2). When defective pipes are discovered, they shall be removed and replaced by sound pipes ; defective joints shall be made tight, and every part of the work in which defects are found, shall be made to conform to the present rules.

Sect. 17.—Joints in iron drain, soil and waste pipes, shall be filled with oakum and lead, and hand caulked so as to make them gas tight, anh they shall not be painted, varnished, tarred or puttied ; the said joints may also be screw joints ; should the work prove to be satisfactorily executed, the Sanitary Inspector shall grant a certificate to that effect to the person concerned.

Sect. 18.—All connections of lead with iron pipes, shall be made with a brass sleeve or ferrule of the same size as lead pipes, which shall be carried inside the ferrule, put in the hub of the branch of the iron pipe and caulked with lead ; and the lead pipe shall be attached to the ferrule by a wiped joint.

All connections of lead pipe shall be by wiped joints.

Sect. 19.—No tile pipe shall be connected with the soil or waste pipe, unless the same be provided with a flange to admit of a proper connection being made.

Sect. 20.—Every water-closet, urinal, sink, basin, washtray, bath, and every tub shall be separately and effectively trapped. This rule shall apply to a set of tubs, but only one trap shall be required for the set.

(1). Traps shall be placed immediately next to the fixtures, and in no case shall they be distant more than two feet from the fixtures.

(2). There shall be only one trap under the water-closet and that immediately beneath the same.

Sect. 21.—The connection between iron and tile pipes shall be made with the best cement, or by any other means approved by the Inspector.

Sect. 22.—Sinks shall be provided at the inlet of such fixtures, with strong metallic strainers to exclude from such waste pipes all substances likely to obstruct them.

Sect. 23.—In no case shall the waste pipe from a bath, tub or other fixture be connected with a water-closet trap.

Sect. 24.—Overflow pipes from fixtures shall in every case be connected with the inlet side of the trap, and above the water.

Drip or overflow pipes from the safety pan under water-closets and other fixtures, or refrigerators, or from tanks, other than those of water-closets, shall be made to run into some place open to sight ; and in no case shall any such pipe be connected directly with the drain, waste or soil pipe.

Sect. 25.—Each water-closet apartment shall be ventilated by means of a shaft or air duct which shall start with not less than 4" diameter and increase one inch as it passes each successive flat and extend at least three feet above the roof and have a suitable cap.

(1). Each water-closet apartment shall be ventilated by means of a shaft or air duct, which shall be at least two inches in diameter in rising from the lowest flat, increasing one inch through each successive storey, but must not be less than four inches, in going through the roof, beyond which it must project at least three feet, and be insulated.

(2). Ventilation may be made through a flue, provided there be no openings in such flue to rooms above, other than for ventilation of water-closet apartments.

Sect. 26.—Every water-closet shall have a cistern supply and in no case be supplied directly from the city reservoir supply pipes.

Sect. 27.—In houses containing one, or more than one tenement, there shall be one water-closet for each family, and a separate cistern for each closet ; in other buildings, however, a group of closets may be supplied from one tank ; and there shall be at least one water-closet to every fifteen inmates.

In buildings where operatives of both sexes are employed, proper separate accommodation shall be furnished for men and women.

Sect. 28.—The overflow pipes from water-closet cisterns shall dischatge into an open sink, or the basin of the water-closet, or where its discharge will attract attention, and indicate whether waste of water is occurring, but not into the soil or waste pipe, or into the drain direct.

Sect. 29.—Valves must be so fitted and adjusted as to prevent wasting of water.

Sect. 30.—No privy pit or cesspool for sewage shall hereafter be constructed within the city or any premises situated within 200 feet of any street wherein there is a sewer and wherein the city water is laid ; nor shall privy pits or cesspools for sewage, presently existing, be henceforth permitted, after May 1st, 1902, to remain in any part of the city where water-closets can be connected with a public sewer in the streets.

Proviso. The Health Department may, however, in exceptional cases, issue written permits for the toleration (during a period not exceeding twelve consecutive months renewable) of privy pits and cesspools for sewage where the nature of the case would make the rigid enforcement of this By-law a detriment to the public health. In all such cases, the following shall be the method of procedure :

1. The owner or agent of any premises, whereon it is desired to tolerate for a limited period a privy pit or cesspool for sewage, shall fyle, during the month of April each year, a demand in writing upon the Health Department for a temporary permit, alleging therein the grounds whereon exception is demanded.

2. The premises in question shall forthwith be inspected by an officer of the Health Department, who shall make a written report concerning the same, to the Medical Health officer upon the following matters :

a. As to the validity of the reasons advanced by the applicant for the exemption from the general law ;

b. As to the construction and condition of the privy pit or cesspool for sewage for which the permit is asked.

3. Upon the receipt of the aforesaid report, the Medical Health Officer, if, in his opinion, the strict enforcement of this law would be detrimental to the health, and

it the condition of the privy pit or cesspool for sewage, for which toleration is demanded, is in conformity with the following article, may issue the temporary permit hereinabove mentioned.

Sect. 31.—Every new privy pit shall be water-tight, of a capacity of 45 cubic feet ; the sides and bottom shall be constructed of cemented brick twelve inches in thickness and well cemented inside with hydraulic cement ; such vault may be constructed of cast iron, the shape or form of which shall be either circular or oblong without angles, and with a concave bottom ; it shall be provided with a ventilation pipe at least 4 inches in diameter, extending from the pit through the roof sufficiently high as to prevent inconvenience to occupants of neighboring houses ; the seats shall have a tight-fitting cover; it shall have an aperture opening exteriorly to allow of cleaning by pneumatic process, such aperture to be two feet by one and a half feet in size ; or else the flooring shall be air-tight and shall have a tightly fitting trap-door comminicating with the pit ; the top of the vault shall be one foot above the level of the ground ; nothing shall be put into such pit, excepting human excreta ; privies shall be located at a distance of 20 feet or more, should the Board of Health deem it necessary, from any house or street ; they shall be emptied when the contents reach within eighteen inches of the top of the vault or whenever the Board of Health deem it necessary ; no offensive smell or gases shall be allowed to escape therefrom. But, in no case shall a privy be allowed within a dwelling-house.

(1). In the case of privy vaults now drained into a common sewer, they shall be isolated by means of suitable traps placed below frost and according to instructions from the Board of Health.

(2). In the case of a new house being built, or one already existing being repaired, wherever there is a public sewer in the street, a water-closet shall be put in, to the exclusion of privy pits.

(3). When a house is occupied by but one family, if there is already a water-closet in the house, no privy pit shall be tolerated on the premises.

Sect. 32.—No steam exhaust blow off pipe shall connect with a sewer directly, or any house drain, soil pipe, or waste pipe ; such pipe must first discharge into a tank or condenser.

Sect. 33.—Cellars shall not be connected with the house drain, unless by a branch pipe, and by special permission of the Department, and according to plans approved of by the Department.

Sect. 34.—A sub soil drain shall be provided when absolutely necessary, and shall be constructed and trapped to the satisfaction of the Department .

Sect. 35.—No trap shall be permitted between the house drain and the public sewer, unless such trap shall have a hand hole for cleaning purposes, and a fresh air inlet pipe, the whole as may be decided upon by the Department.

Sect. 36.—Drains in yards shall, in all cases, be trapped below frost, that is to say : four feet at least under ground.

Sect. 37.—The inspection of drains on private property shall be under the exclusive control of the Department.

Sect. 38.—Gas companies are obliged to place a stop cock to every main pipe.

Sect. 39.—Any person contravening any of the provisions of this By-law, shall be liable to a fine with or without costs, and in default of immediate payment of the said fine with or without costs, to an imprisonment ; the amount of said fine, and the term of said imprisonment to be determined by the Recorder's Court, at its discretion ; but the said fine shall not exceed forty dollars, and the term of imprisonment shall not exceed two calendar months ; the said imprisonment, however, to cease at any time before the expiration of the period fixed by the Recorder's Court, on payment of said fine or fine and costs ; and where the infraction is continuous, such infraction during each day shall constitute a separate offence.

This By-law will go into operation on the first of September next.

NATIONAL ASSOCIATION OF MASTER PLUMBERS AND STEAMFITTERS OF CANADA.

The sixth annual convention of the above Association was held in the Temple Building, Toronto, on June 26th, 27th and 28th. The chair was occupied by the President, Mr. W. H. Meredith, of Toronto. The following persons were in attendance at the meeting :—Thomas Moll, Ald. Lamarche, Capt. Joseph A. Giroux, Thomas Christie, John Watson, Montreal ; H. Hogarth, W. Mansell, W. H. Meredith, J. B. Fitzsimons, K. J. Allison, W. J. McGuire, George Cooper, Alex. Fiddes, J. H. Wilson, R. Ross, Alex. Purdy, J. J. McKittridge, Toronto ; F. G. Johnston, John McKinley, H. A. Knox, Ottawa ; H. Mahoney, Guelph, Ont.; John H. Neelands, Barrie, Ont.; Frank Powers, Lunenburg, N.S.; James Boxall, Lindsay, Ont.; Adam Clark, J. Wallace, A. Rogers, Hamilton ; Peter Shiells, Kincardine, Ont.; George Ross, Brockville, Ont.; S. King, Ingersoll, Ont.; James Pennington, Windsor, Ont.; W. Sievewright, Petrolia, Ont.; Charles T. Bull, James Williams, St. Thomas, Ont.; M. B. Squires, Windsor, Ont.

On behalf of the City Council the delegates to the convention were welcomed to the city by Aldermen Cox and Loudon, of the reception committee of the City Council. Mr. James Wilson, President of the Toronto Association, also extended a welcome to the visiting delegates. Mr. Hogarth, Chairman of the Reception Committee of the National Association, introduced the following gentlemen representing the supply interests : Messrs. Fred. Somerville, W. C. Allen, Chas. W. Chandler, Alexander Fleming, Ontario Lead & Wire Company ; Charles J. Britain, James Morrison Brass Mfg. Co.; A. A. McMichael, Andrew Mann, E. A. Rogers, The James Robertson Company ; W. L. Helliwell, T. B. Alcock, E. J. Brewer, Gurney Foundry Company ; Andrew Taylor and W. Taylor, Dominion Radiator Company ; H. W. Anthes, Toronto Foundry Company.

In response to the request of the President several of these gentlemen addressed the convention, wishing the Association success in its work and expressing the hope that its deliberations would result to the advantage of the trade as well as of the supply houses. Mr. J. J. McKittrick made the suggestion that the Association should draw up a model plumbing by-law for the guidance of the municipalities throughout the country.

The President in his report referred to the good feeling existing between members of the Association and the manufacturers and jobbers. He pointed out the necessity for systematic organization and the appointment of a permanent secretary who should devote special attention to this work. The difficulty in the way of carrying out this suggestion was to secure the necessary funds. The necessity of educating the members of the Association to do first-class work at a fair price and to avoid underbidding each other was also touched upon. The President expressed the opinion that the greatest evil in the plumbing trade to-day is over-keen competition among bidders, resulting in scamp work.

The Vice-President, Mr. John McKinley, in his report drew attention to the neglect on the part of city councils throughout Ontario to adopt proper plumbing and sanitary by-laws. This neglect, he claimed, was due to defects in the provincial laws. He suggested the appointment of committees to see that these defects are remedied, so that it will not be possible as at present for unskilled persons to engage in plumbing work.

Mr. Frank Powers, Vice-President for New Brunswick and Nova Scotia, reported that the past year had been a prosperous one for the plumbers in the Maritime Provinces, and that the present outlook was promising. He stated that well-founded complaints had been made against the supply houses for selling to consumers, and suggested that the Association devise means for dealing promptly with cases of this kind. To this end the formation of Provincial Associations was recommended. The benefits which would accrue from the formation of such Associations would be an increase in the membership of the National Association, the privilege to members of attending quarterly meetings, the securing of sanitary

legislation applicable to the towns as well as the cities, and the removal of any jealousy which may exist between the master plumbers in the city and country. The report stated that a Local Association of Master Plumbers would probably be formed at an early date at Sydney, C. B.

The report of the Secretary, Mr. W. L. Mansell, contained the following list of places where Master Plumbers' Associations exist, together with the membership in each case:—Halifax, 21 members; Sydney, C.B., St. John, Fredericton, Quebec, Ottawa, Kingston, Hamilton, St. Catharines, 12 members; Montreal, 34 members; Toronto, 23 members; Windsor, London, 9 members; St. Thomas, 2 members; Guelph, in affiliation with Toronto, 1 member; Sarnia and Chatham in affiliation with Windsor, 1 member each; Winnipeg, 8 members; Vancouver, 11 members; Barrie, in affiliation with General, 1 member.

The report stated that the local Associations were in a prosperous condition, and that good feeling prevailed between the Associations and the manufacturers.

Mr. Jas. Pennington, as Vice-President for Ontario, expressed regret that it had been found necessary to discontinue the publication of the "Bulletin," and asked whether it would not be possible to charge a subscription of $1.00 per year. It was suggested also that the travellers representing the supply houses should be furnished with literature by the Association for distribution to the plumbers throughout the country, urging them to become members.

The various reports were referred to the Committee on Resolutions.

Messrs. F. Powers, Joseph Pennington, F. G. Johnston, John Watson, W. Mansell and John McKinley were appointed a committee to consider and report regarding the advisability of forming Provincial Associations.

At the evening session the Committee on Resolutions reported recommending that the question of appointing a permanent secretary be referred to a select committee; approving of the suggestion of Vice-president McKinley for the appointment of a committee to consider grievances, as well as his recommendation regarding Provincial Associations and sanitary laws, and suggesting the appointment of a select committee to consider and report on the first of these recommendations. It was recommended that the report of the Vice-President for Nova Scotia be adopted, also the report of the Legislation Committee, and that the report of the Vice-President for Ontario be referred to a select committee.

The Apprenticeship Committee's report recommended that an apprentice should serve five years before being recognized by the Association as a journeyman; that all present and future apprentices shall receive at the end of their apprenticeship term a certificate of the Association from their employer as a proof of their ability, and that the matter of their wages be referred to the Local Association for adjustment. After some discussion the report was adopted.

A motion by Mr. Powers that a committee be appointed, consisting of three members from each province, to consider the question of sanitary laws and endeavor to secure the enactment of such laws, was adopted.

Mestrs. Allison, Fitzsimmons and Mahoney were appointed a committee to report with regard to the advisability of appointing a paid secretary.

At the morning session on the second day, Alderman Lamarche, of Montreal, addressed the convention and explained the leading features of the new plumbing by-law, which has recently passed the Council of that city and will go into operation on September 1st.

The Committee re the appointment of a permanent secretary reported recommending that the appointment be made at a salary of $200 for the first year. After some discussion action upon the report was deferred until the following day.

On the adjournment of this session at 1.40 p.m., the delegates were given a carriage drive to points of interest in the city as the guests of the City Council.

In the evening the Annual Association Banquet took place at McConkey's restaurant, and notwithstanding that the weather was uncomfortably warm, was largely attended. The chair was occupied by Mr. J. H. Wilson, President of the Local Association, having on his right the President of the National Association, Mr. W. H. Meredith, Alderman Wood, Alderman Lamarche and Mr. H. W. Anthes, and on his left Mr. A. E. Kemp, M.P.; Mayor Howland, Mr. Edward Gurney, Mr. J. H. Patterson, Mr. Andrew Mann and Mr. Alex. Saunders. Messrs. Kemp and Gurney responded to the toast, "Our Country and its Manufacturing Industries." Mr. Meredith, Alderman Lamarche and Mr. Frank Powers replied in suitable terms to the toast, "Our Guest—the National Association," proposed in a humorous speech by Mr. Anthes. "The Mayor and Corporation," brought a response in French and English from Mayor Howland. "The Manufacturers and Supply Trade," brought responses from Messrs. J. H. Patterson, Adam Taylor, H. W. Anthes, Alexander Saunders, Alexander Fleming, T. B. Alcock, Charles Morrison and Andrew Mann. Mr. Grant Helliwell, President of the Ontario Association of Architects, and Mr. Robert Harrison, President of the Journeymen Plumbers' Association, replied on behalf of "Sister Associations." The "Local Master Plumbers," proposed by Mr. Frank Powers, of Lunenburg, N.S., was responded to by Messrs. J. J. McKittrick, J. H. Wilson, and K. J. Allison, of the Toronto Association. Captain Giroux replied on behalf of "The Ladies." A pleasing feature of the evening's proceedings was the presentation of a gold ring set with diamonds and bearing the masonic emblem to Mr. Fiddes, in recognition of the many valuable services which he has rendered for years past to the Local as well as the National Association.

At the Friday morning session Messrs. John Watson, Montreal; Frank Powers, Lunenburg; and J. G. Johnston, Ottawa; were appointed a Nominating Committee.

After some discussion it was unanimously resolved, on motion by Mr. Powers, that the convention next year should be held in Halifax.

It was resolved to organize Provincial Associations on the basis of a constitution recommended by the special committee appointed to consider this question, such constitution being an alteration of that of the National Association in such a manner as to make it applicable to the provincial organizations.

After discussion it was resolved to leave with the Executive Committee the question of the advisability of appointing a permanent secretary.

The report of the Treasurer, Alderman Lamarche, was presented, showing receipts $303.21; expenditures $226.61; balance in hand, including previous balances, $293.22. The Auditing Committee reported the Treasurer's books correct, and a vote of thanks was tendered to that official.

A vote of thanks was also tendered to the Local Association and to the City Council, to the retiring President, Mr. Meredith, and to the retiring Secretary, Mr. Mansell.

The election of officers resulted as follows:—Past-President, W. H. Meredith, Toronto; President, John McKinley, Ottawa; Vice-President, Frank Powers, Lunenburg, N.S.; Secretary, H. A. Knox, Ottawa; Treasurer, Ald. Lamarche, Montreal; Vice-President for Ontario, W. Mansell, Toronto; Vice-President for Quebec, John Watson; Vice-President for Nova Scotia, G. A. Perrier, Halifax; Vice-President for New Brunswick, James Walker, St. John; Vice-President for British Columbia, J. H. Wilson, Toronto; Vice-President for Manitoba, Capt. J. A. Giroux, Montreal; Chairmen of Committees—Apprenticeship, R. Ross, Toronto; Legislative, E. B. Butterworth, Ottawa; Sanitary, J. W. Hughes, Montreal; Essay, George Morton, Yarmouth, N.S.; Sub-Executive—President McKinley, Ald. Lamarche, H. A. Knox, John Watson, F. G. Johnston.

After the close of the last business session a visit was paid to Government House, where a group photograph was taken, after which the members and visitors proceeded by electric car to Long Branch and gave themselves up to an afternoon of enjoyment.

Branch Office of the CANADIAN ARCHITECT AND BUILDER, Imperial Building.

MONTREAL, July 13th, 1901.

ARCHITECTURE AT THE UNIVERSITY.

A course in Architecture has now become quite common in the calendar of universities so that any discussion on the benefits to be derived therefrom should be of interest to architects. There are at the present time some nine or ten universities in the United States giving such a course so that there should be sufficient evidence to show the pros. and cons. of the architectural school. The work done at such universities as Columbia, Cornell and Pennsylvania to say nothing of the now almost universally known Massachusetts Institute of Technology, is beyond the experimental stage and has been of undoubted benefit to the standard of Architecture in the United States. Comparatively speaking, however, the work in these colleges is only in its infancy compared with what undoubtedly it should and will be. Architecture to be at its highest must be a live art, must have vitality of its own time and country. The architectural student is first taught correct proportion, and for this purpose is thoroughly grounded in the work of the Greeks, but it should be instilled into the student at the same time that it is not in copying the ornament and details of the best periods of Architecture that anything really great can be produced, but on having gained the power of perceiving the right and proper proportions, to be able to design and use ornament, etc., of local interest. Where are there such opportunities for such work as in the architectural college? Ornament should be taught from the best examples, then the rules governing them applied to the design of local flowers, plants and trees.

The Egyptian and the Greek carried the design of the palm and the acanthus to perfection, plants growing at that time and in that country. Let students be taught the principles that underlie all that is considered, after centuries, great in Architecture, and see the reasons, the why and the wherefore of its greatness, and apply these principles to their own work, but using the materials and ornament expressive of their own time and locality. Let it also be instilled into them that what may be suitable in one district may be very bad Architecture in another, and that a universal Architecture would be of necessity bad Architecture.

It is commonly conceded that a painter or sculptor must not slavishly copy the works of the great masters, but must take from nature and express it on canvass or in marble. The architect, on the other hand, is mostly satisfied to copy, more or less, his detail, using ornament expressive of another country and of a bygone age. As long as this lasts there can and will be no real live Architecture, and it will be to the architectural college that we will probably have to look for the first signs of improvement.

It is necessary, in order to make the course a success, that it be brought up to the highest standard, as unless a course is up to a certain standard students will not attend, and it soon becomes a financial as well as a teachers' failure. For instance, at McGill University, where there has been an architectural course since 1896, the staff of teachers has been limited, and although this course is allied to Applied Science, the number of teachers is small to bring the work to the standard suggested. The successful colleges in the United States usually have a staff somewhat as follows:—

1. Professor in charge of the department.
2. Assistant Professor, Design and Ornament.
3. Instructor in Freehand, Geometry and Perspective.
4. Instructor in Water Color and Pen and Ink Work.
5. Instructor in Materials and Structural Design.
6. Instructor in Modelling.
7. Instructor in Landscape Architecture.

Besides studies gained from teachers in other departments on Elementary Chemistry, Geology, Botany, Mathematics and laws relating to Building. It is almost impossible with a staff of two or three to bring the course up to the highest pitch with all the various subjects necessary in Architecture. In Medicine the various practising doctors give lectures and hold clinics, and if the same thing was in vogue to the same extent in Architecture we feel sure there would be a vast improvement. It is the day of specialists, and it is necessary that a staff of specialists be employed as teachers in any course in order that it be successful. The various colleges have a great daty to perform in raising the standard of Architecture, and we trust to see McGill do its share for Canada.

THE CITY BEAUTIFUL.

"The perfect opportunity of the architect will not come until men dream of, and work earnestly and rationally for cities beautiful." The above quotation is applicable at the present time in Montreal when there is so much talk of:—

1. Harbor improvements.
2. Raising the tracks of the Grand Trunk Railway.
3. Underground wires in connection with the new electric light contract.

In respect to the raising of tracks of the Grand Trunk, which will be an enormous expense to the company and at the same time an eyesore to the community, we would like to suggest as an alternative scheme that the rails should be run from Victoria Bridge around the space at the head of the Guard Pier along the lower side of Mill street across the canal at or near Black's bridge and the back of the buildings facing Common street to McGill street. The tracks from the canal to McGill street to be elevated. By this scheme the railway company would save the level crossings, save the best part of the expense, if not all, of changing their present tracks, as the sales of their property on which their tracks are now would probably more than pay for their extra work, and have their station near their new offices, and save several minutes on the traffic over the bridge. The community on their side would save the spoiling of their property on each side of the railway which runs through the heart of the city and the station would be equally if not more handy.

We would commend this to the thoughts of the City Council and the railway company.

In respect to the placing of the wires underground as a necessary part of the contract for lighting the city to whichever company gets it, we would like to urge the necessity of it as a safeguard for the public and also from the point of disfigurement of the city as a whole, for the best as well as the poorest districts are overrun with these wires to the detriment of all good Architecture. It is the duty of the City Council to see that this clause is inserted in the contract, and it is also the duty of the citizens to see that the Council fulfils its duty or to know the reason why next February.

"If members of architectural societies would meet for the discussion of the aesthetic possibilities of their own communities, they would do much to substitute in themselves a broad for a narrow view and popularly to educate to appreciation of, and wish for, cities beautiful. To do this is the architects' duty, and upon success in it rests his hope." We commend the above quotation to the

thoughts of the Councils of the various architectural societies or clubs in Canada. It is time that the art interests of the country be considered, and the architect has his duty to perform to his city as well as to his clients.

P. Q. A. A. NOTES.

The P.Q.A.A. has issued a catalogue of the books in the library of the Association which will be found very useful to members wishing to refer for information to the library. We regret to say that the library has not been used to the extent that it should be, considering the value of many of the books. We would, however, like to suggest the necessity of adding to the collection from time to time, as the 200 volumes should only be the beginning of the collection. We would further like to suggest that such standard magazines as the "Builder," of London, and the "Brickbuilder," of Boston, be added to the list of magazines on the table. We trust that by so enhancing the usefulness of the library the members and students will show their appreciation thereof by making use of the books, and thus encourage the Association to add to the list of both magazines and books.

THE NEW PLUMBING BY-LAW.

The new plumbing by-law of the City of Montreal was passed by the City Council on June 12th last, and will come into force on the 1st of September. A copy of this by-law is printed in the present number of the Canadian Architect and Builder, and it would be well for architects, plumbers and others interested to make careful study of its provisions. One of the chief changes appears to be that "Any person engaged in or working at the business of plumbing prior to the passing of this by-law, and desiring to engage in or work at said business, either as a master or employing plumber in the City of Montreal, shall on or before the 1st of September, 1901, apply to the board of examiners hereinafter provided for, to be examined as to his qualifications for such business."

BRITISH COLUMBIA LETTERS.

No. VI.

In a brand new country, such as is this Western Province, Viator finds many little idiosyncracies to amuse, surprise, or perchance, to puzzle him; one of the most strongly marked of these is a curious objection to any criticism that is not merely flattery. It would appear that, in the juvenile stages, communities like persons are impatient of anything that may be construed into correction. The Parochial Patriot swells visibly with satisfaction when we express admiration of the physical beauty and natural advantages surrounding the youthful community of which the P. P. is a unit, and seldom does he fail to remind the speaker that "we are so young, you know!" as though to imply that our admiration might be augmented somewhat on that account. If, on the other hand, it is pointed out that the newest and best of methods might be reasonably expected to prevail in the newest and best of towns, whereas the very reverse appears to very frequently be the case, our friend the Patriot promptly advances (with a somewhat injured air) the same old well-worn apology for all shortcomings, "We are so young, you know!"—which certainly savours of the blowing that is both hot and cold.

The Press is largely responsible for this beam in the public eye—for this singular local vision which regards its own failures through the wrong end of the telescope and its successes through "a pair of double million magnifiers," as Sam Weller would have said—for the Press publishes the most reckless statements respecting trade or the prospect of the building season, the output of the Yukon, or the probable growth of "our" population; the reports regarding the superior magnitude and beauty of our buildings are often simply astounding, and the notice (probably well paid for) of a few works of art causes almost as great a strain upon the supply of adjectives as does the so-called report of an opposition political meeting.

Quite recently a paragraph appeared in a local newspaper stating that some exceptionally fine pictures, the work of leading European masters, were for sale in such and such a place on Hastings street. Though we should have known better by this time, we went to the place indicated, only to discover these "works by leading European masters" to be the most ordinary of catch-penny productions in very gilt frames, evidently prepared for sale in job lots by painters who were certainly in no sense masters. This being but too obvious, why should so misleading a description be published? If intended in the nature of a critique it was preposterous; if it was a mere advertisement, then it should have appeared in such a manner it could not have been mistaken for anything else. This sort of thing occurs frequently and may be intended for news, but is nevertheless objectionable to those who prefer facts to fiction.

About the same time appeared a so-called description of a nearly completed church, a description which could not have been pitched in a higher key had the theme been Chartres, St. Ouen, York Minster, Canterbury or Cologne. A little later the same journal gave vent to an agony in several columns dedicated to, we believe, The Stately Homes of Vancouver. The writer simply lost his way in the most astounding maze of terms from which he was evidently unable to extricate himself; the meaning of it all, if there was any meaning—and we cannot state positively that there was—seemed to be, that Vancouver as a whole was housed like the merchant princes of Venice, with a touch of the best of England's most famous country house architecture. A somewhat extraordinary effusion, indeed, which read rather like an architectural Book of Revelations.

What good can come of all this nonsense? Why should such gloria reporter rhetoric be so revelled in whenever the theme be the completion of a two or three-storey block of prosaic shops and offices, the auction of a few tenth-rate paintings (in very gilt frames), or the opening, say, of a church, over the whole of which is written in big bold letters an avowed expediency and cheapness? In how much better taste would it be to say that the shops were large and well lighted, the offices convenient—that paintings by Messrs. So and So, representing certain scenes in Italy, the Tyrol and so forth, might be seen by those interested in such matters at such a place—instead of describing the church in the most grandiloquent language with a reckless misapplication of architectural terms calculated to drive a glossographer crazy. Instead of all this riot of words bereft of meaning, why not simply state that the plan is a Latin cross, the apse circular; to give the general dimensions of the nave, aisles, choir, transept, etc., together with a description of the various materials used, the cost of this and similar structures in the locality, to indicate in what direction the quality of our building may show advancement. Of course more of this would be criticism, but it would certainly be useful, because truthful, information, as opposed to ignorant and irresponsible laudation, which makes us inclined when referring to it to act upon Sir Toby Belch's instructions, "Let there be gall enough in thy ink, tho' thou write with a goose pen, no matter!"

Probably the Rhetorical Reporter thinks with W. Hanibal Chollop that "Our backs is easy riz, and we must be cracked up," and no doubt he knows his public—none the less it would be well if he came to realize that there are very many exceptions to the Chollop rule.

So general is the dislike to criticism that the then Executive of the Arts and Crafts Association caused it to be recorded on their minutes that they were of the opinion that no member of the Association should criticize the work of fellow members in the public press or magazines! Criticism being absolutely barred all notices of future exhibitions will at best become merely descriptive catalogues, though descriptive they can hardly be, for it is impossible to be said to describe a picture if all reference to its qualities be omitted. Thus it will be seen that we shall either have no notices worth having, or else the flowery flattery before referred to.

Painters may come and painters may go, but Art goes on for ever, and criticism will ever be found in close

attendance upon her. It has been said that taste is the faculty that enables us to distinguish the merits of a work apart from our own likes and dislikes. This faculty must, however, be carefully cultivated before it becomes taste, for knowledge is the foundation of correct taste. The first essential in a critic is therefore cultivated taste or knowledge, and the deeper his knowledge the less likely is he to be biased by predilection. A critic need not of necessity be a performer, for the perceptive faculty is not always accompanied by the creative. To better illustrate my meaning—"A" studies landscape painting in certain schools and adopts the methods peculiar to one of them, and in time becomes a distinguished painter, probably with a strong bias towards his favorite school, and it not unfrequently happens that he has little toleration for any other. "B," on the other hand, finding that a lack of technical and creative power prevents him from hoping for any measure of success as a worker, turns his attention to the several schools and, having at length absolute merits of landscapes painted in any school. The opinion of "B" is necessarily of greater value than that of "A," though his work might be in every sense inferior to that of the latter. The opinion is commonly held here that a critic who cannot with his own hands produce something better than the object he criticizes, is not qualified to express judgment. This wholly erroneous contention is so frequently encountered, we have dwelt upon it at some length. One may as well urge that the architect who cannot wipe a lead joint, dowel a stone or lay a few courses of brick work in Old English Bond, is incapable of judging the work of the different trades. It is well known that few performers can justly guage their own capacity, whereas a capable critic knows exactly the extent and measure of his knowledge.

It seems to us that what we all most desperately require is a standard of criticism. Raise that standard and you raise the aim of artsmen and craftsmen. The public, too, is gradually taught by able criticism to discriminate between that which is fairly good and that which is downright bad, which would be a change indeed. To betray any impatience under fair criticism is to reveal an inability to be introspective, to be, in other words, childishly thin-skinned. Honest criticism, even if it is proved to be not altogether sound, can do no one harm and may do good, for it should cause the producer of the object criticized to carefully analyse the work in question if only to reassure himself that he is right. Of course we are assuming throughout that our critic is a critic, and not merely the ordinary ignoramus talking through his hat, as the vernacular elegantly expresses it.

Our object in touching upon this question of criticism is mainly to draw attention to the remarkable absence of it in this country, and the substitution of absurdly high and often unqualified praise, amounting to gross exaggeration on the one hand, or downright vehement abuse on the other—both being equally objectionable—also to the scarcely less remarkable absence of any fixed standard of excellence in most things, more particularly in relation to matters of taste. We do not intend to try in a paper of such necessarily narrow limits as to quantity, to assign reasons for the existing state of affairs; it is sufficient to note the evil and do something towards remedying it, and the initial step is to improve our own standard of excellence and reconcile ourselves to the cool surgeon-like knife of fearless criticism. How can we learn if we will not be taught, and why should the producer of a work of art so frequently resent even the inference that faults may be discovered in his work? One would suppose Art to be in no sense public property, and her votaries the only people on earth exempt from human weaknesses, whereas Art is very dependent indeed upon the said public, which is in its turn mainly, if not entirely, dependent upon published criticism for its education, when it has any. If anyone produces work for sale and for exhibition it is certain to be more or less closely analysed, and it will behove us to remember that in the great majority of cases the critics are right. No doubt at times eccentricity is mistaken for genius, and vice versa. There is such a flagrant instance of fallibility as the passing over of such a man as J. W. M. Turner, whose extraordinary gifts were long unrecognized, and no doubt respectable mediocrity occasionally turns down much greater ability. Which all goes to prove that knowledge is the foundation of taste, and that when a man like Turner does appear in this unregenerate world and works in an atmosphere we know not, and whose work speaks in a language that is strange to his generation, it merely means that the world has to be educated up to his higher standard before he can be understood. It is hard on the genius, but extremely good for the millions of fools.

Critics constantly disagree, but most usually on questions that time alone will correctly answer, but the criticism which concerns us is of a comparatively elementary kind; too frequently our critic's main difficulty is to find something good to say for us, the faults being all too easily found. When adversely criticized let us smother our wounded vanity and endeavor to remember that our work will not be made one whit better by our angrily declaiming that the miserable creature who says the arm of our Eros is out of drawing, knows nothing about the matter, or that Jones always was a hopeless ass, that he is a hopeless ass, and that he always will be a hopeless ass, because he referred, not unkindly, to the mustardy tones of our greenery-yellery landscape, or because he objected to the clever manner in which our impressionist picture avoids all the real difficulties of painting; or that the plan is bad and the composition commonplace of our competition design. Such expressions are not altogether as pleasant to hear as more flattering but less truthful ones might be, but if we are endowed with an ordinarily full measure of that uncommon thing called common sense, it is ten times more likely that we will find if we search that the fault lies with our work and not with those whom we have heard grandiloquently alluded to as "our traducers."

It must be borne in mind that only a very minute portion of the people ever devote a moment's thought to what constitutes good or bad taste, that a smaller proportion still are artsmen and craftsmen, and that few, very few, only of these really fully exercise their powers of observation and learn how to discriminate with some accuracy. Most Art is commonplace and when someone rises above his fellows and mediocrity, Envy endeavors to reduce the little eminence to a mole hill, while injudicious flattery tries to elevate it to the Himalayan heights of Heaven-born genius. Then comes the sober critic who gives us the true attitude, in inches. It is this matter-of-fact-surveying sort of process that some people find so hard to bear. The nihil me tangere attitude that is frequently adopted always reminds us of the inebriated Scotchman who having tumbled into an open grave overnight, was awakened in the early morning by the village band, which he mistook for the last trump, and emerging from his temporary retirement and finding himself quite alone, the only one of the elect in short, expressed it as his opinion that it was a puir puir show for Abergeldy. But think of the ultimate disillusionment which came to the unfortunate man. Does it ever come to those artists of the type referred to? It would do the vast majority of our artists no end of good to sit in a sort of Trial Eight, as it were, and to learn to stoically endure the pungent remarks passed on their efforts, the impassioned exortations and despairing tones of our honest, capable, hard-working coach. Unless prepared to learn we cannot improve; we cannot learn without submitting to criticism, and we often regard our mentor as hard and unsympathetic, when the truth is that his standard of excellence is higher than our own. With corrupt or incompetent judges, justice is but hardly served, so from incompetent critics little can be learned of the truth, and as we are on this earth primarily to gain knowledge through long-suffering and bitter experience, let us pray for fearless, cultivated criticism, and to be stiff enough not to whine when our vanity and self-esteem is made to suffer a little healthful sensation of smart and tingle.

HANGING PAPER ON CEILINGS.

When the face of plastered walls is not good enough to turn out a good job of distemper a fine new surface is attained by lining them with blank lining paper. In papering a ceiling with lining paper it is better says the Painters' Magazine, that the edges of the lengths should barely meet than that they should overlap. In cutting ceiling papers to the angles formed with the wall, the less they are allowed to lap on to the wall the better. Half an inch or so is quite sufficient; because when a couple of thicknesses of paper are on such places they generally "spring" unless they are very strongly attached.

If there are any cracks in the plaster they need even more attention than in cases where distemper is to be applied direct to the ceiling. In stopping a crack the object is not only to fill it up. With cracks in ceilings generally, one edge will be found to be slightly drooped below the other. In this case the crack requires to be cut out before stopping. If it were not, after lining it would show as a sharp, irregular edge. The only remedy is to enlarge the crack, more or less, according to its importance, by scraping or cutting it out with a stopping knife. For stopping large cracks a stopper—a knife with a blade about three inches wide—is a very serviceable tool. It might be worth while remarking here that where walls or ceilings are to be finished in distemper, without previous papering, it is best, in stopping, to discard steel knives, which scrape and disfigure the face of the plaster in a way which invariably shows through the subsequent mat of distemper. Use instead a tool made of wood and shaped like a stripper, and use it in the same way. As to the stopping, it is generally made of plaster of paris with whiting added. Sometimes, when convenience renders it necessary, some add a few drops of size to the mixture to prevent its too rapid setting. It is surprising to one not familiar with it what an effect the addition of size has; but, at the same time, it is generally considered that the stopping is better without this addition. Always wet cracks, etc., thoroughly before putting in the plaster, otherwise it will not adhere for any length of time.

But to return to the paper hanging. In lining a ceiling start the paper from the wall nearest the window and work towards the door. The reason of this is that if there should be any overlapping edges they will be facing the window and therefore not visible from the door or main part of the room—that is in a room of ordinary shape. If, on the other hand, the paper were hung to the window, overlapping edges, which, even with the most careful workmen are bound to occur, throw a shadow line, which, under usual conditions, would be almost certain to catch the eye.

In papering a ceiling proceed in the same way as for walls. Find the length of the pieces of paper to go from wall to wall, and cut the number required. Arrange a scaffold so as to have the plank running close up to, and parallel with the wall to which the first length is to be hung. Ceiling lengths are generally longer than a wall requires. Fold them with a long fold at the top—or starting end—and a very short fold at the bottom or finishing end.

The first length has no previous one to match to. We shall, therefore, for convenience sake, consider it hung, and will describe the manner of getting the second up, which description will apply equally well to all those that follow. And, first, as to pasting. In this, as a rule, there is not much variation necessary, except when the lengths are very long. Say men are on a moderately sized room. Make the first fold as large as the board will allow, and the bottom end one much smaller. The next operation is to hang it. In hanging ceilings a roll or portion of a roll of paper is necessary as a support to the pasted lengths. Insert this roll beneath the top portion of the pasted length on the board and lift and carry it on the roll to the scaffold. Have the plank running parallel with the length previously hung, and have the inside edge of it directly under, and in a line with the outer edge of the last length hung. This is important in order to be directly under one's work. Do not have the scaffold too high, but sufficiently low to allow the body, arms and eyes full play. Start from the right hand wall with your back to the last length on the ceiling. With the right hand take hold of the extreme corner of the length by the inside edge. Now open the first fold and move the supporting roll about until we have two or three feet between the two hands. If we succeed in placing these two or three feet on the ceiling correctly the remainder of the length, however long, if the ceiling be true, will find its place almost as a matter of course.

Hold the length up to the ceiling, with arms outstretched, and work it about, within an inch or so of the ceiling until we have settled the correct place in which it is to go—but do not, on any account, allow it to touch yet—and, when this is settled, with the right hand match and place the near end corner. Now we have to see to the portion directly over the supporting roll held by the left hand. Though the right hand should not be allowed to shift yet, it must be used as a pivot for the portion over the left hand to be correctly worked into place. When the edges of the space between the two hands match correctly, temporarily press the roll on the ceiling, run the right hand along the edge, to fix the match, and then, still holding the roll in the left hand, firmly against the ceiling, take the brush from the pocket and brush down the first foot or two of paper. If the length be correctly started in this fashion, all we have to do is to move the supporting roll along under the paper, a foot or more at a time, and brush down by a brush stroke on the middle of the length, followed by others towards the edges, keeping the roll in the left hand always an inch or two away from the ceiling.

If the first foot or so of edge is perfectly parallel with the edge of the previous length, the whole length will brush into its place without the least trouble. But if the edge over the left hand is the least bit overlapped, whilst correct at the extreme starting point, it will mean that the overlap will gradually increase as the length is brushed on, until, at the finishing end, it may be a half inch or more overlapped, and the whole match consequently bad. If, on the other hand, it overlaps slightly at the extreme starting-point, and is just where the supporting roll is, it will be found that before many more feet of the paper is brushed on the edges of the length previously hung and of that being hung will appear to be growing gradually wider apart, leaving a considerable space of the ceiling bare and necessitating either that the length be taken off and rematched or else subjected to a considerable amount of brushing and twisting, which will have to be repeated in hanging subsequent lengths.

Never allow the pasted side of the paper to touch the ceiling until it is brushed into its place. Keep the roll supporting the pasted length always a few inches away from the ceiling. When we come to the small end fold, however, the roll may be temporarily placed firmly against the ceiling whilst the fold is being undone.

Papering a large ceiling is really little more difficult than doing a small one, the only extra trouble being in handling the large body of pasted paper. But the secret of success is to correctly match the first foot or two. The method of folding the pasted lengths needs to be varied somewhat. The method generally adopted by the best paperhangers I have known is rather difficult to describe, but is as follows: Paste and fold the first part resting on the board, but partly unfold it back until the extreme end rests on the turning point of the large fold. The first long fold is, in fact, half unfolded again. This gives us two short folds with a portion of the pasted side upward. Draw the length along and paste, fold, and again half unfold this second portion. These short half-folds may be continued as long as necessary, the final fold being an ordinary short fold in the opposite direction. Now, to hang the length, place the supporting roll directly under these numerous half-folds. The left hand, with the roll, supports the pasted folds, which must not be allowed to touch the ceiling, whilst the right hand is at liberty to fix the matching edge in its place and then brush the paper down, the short folds on the supporting roll gradually unrolling of themselves as the operator moves along the plank.

NON-INFLAMMABLE WOOD.

The degree of excellence to which the fireproofing of modern buildings has been carried, is evidenced by the severe tests which have recently been made in the United States and other countries with wood treated by the electric process of fireproofing. This process is the latest development in the science of rendering wood non-inflammable, and has been adopted by the British and United States naval authorities after a series of the most exhaustive comparative tests with every known method of fireproof construction in the line of material that could be utilized as wood in the building of warships. It has been endorsed by leading architects and chemists in this and other countries and has been used in some of the most modern buildings recently constructed.

When the lumber is received at the fireproofing works it is piled in conical shape on iron cars with 3-8 lath between each layer of boards. After the load has been made up 105 ft. long, it is drawn into a cylinder by a one inch cable, after which the door is closed and locked. Then a steaming process takes place inside the cylinder, thus opening the pores of the wood. The sap is extracted from the wood and drawn from the cylinder by vacuum. While this is taking place inside the cylinder the chemicals in the large tanks overhead are going through a heat ng process. After the lumber has been softened to a certain degree and the pores thoroughly opened, the heated chemical is allowed to pass by gravity into the cylinder until it is filled, after which the pressure pumps are set to work and are kept working until the pressure has gained 150 pounds to the square inch. The chemicals in the cylinder are then forced back into the overhead tanks by means of air pumps, the doors are opened and the lumber drawn out of the cylinder and transferred to dry kilns, where the process is completed.

This electric process of fireproofing is at present carried on by three companies in the United States, one in London, Eng., and the Electric Fireproofing Company, of Canada, Limited, with office and works at Cote St. Paul, Montreal. A representative of the Canadian Architect and Builder recently visited the works of this company, which are situated at Cote St. Paul, on the Lachine Canal. The Grand Trunk Railway Company have siding into the premises, so that every facility for shipping by water or rail is available. The property covers an area of 7 1-2 acres, and the factory is built of solid brick with roof supported on steel columns and girders. The building is divided up into a cylinder-room, engine and pumping room, boiler room, coal room, chemical-room, storeroom, office, two dry kilns and transfer table. The building is so laid out that double the plant can be added as the business increases. The cylinder-room is 123 feet long by 32 feet wide, and contains two cylinders 105 feet long by 7 feet in diameter, capable of holding 15,000 feet B. M. of lumber each at one charge. Above the cylinders are three large feed tanks, each having a capacity of 26,330 gallons. The tanks contain the fireproofing solution, which is pumped into the cylinders under pressure. The doors of the cylinders are fastened by radial steel bolts weighing about ten tons, and are operated by two men in a few seconds; these doors have to stand at times an internal pressure of from 200 to 300 pounds per square inch. The boiler-room is 37 feet by 24 feet and contains two Babcock & Wilcox high pressure 75 horsepower boilers. These boilers supply steam to the cylinders, pumps, dry kilns, etc.

The engine-room is 39 feet by 37 feet, and contains a 75 horsepower Corliss engine; steam winch, 40 horsepower, for operating yard and lifting 8,000 pounds; one vacuum and pressure pump, 16 x 20 x 24 in.; duplex water pump, 8 x 7 x 12 in., connected to canal by an 8 inch water main; two duplex pressure pumps, 5 1-2 x 3 1-2 x 5 in., high pressure to cylinder; one pump for suction service to feed tanks, 5 1-2 x 3 1-2 x 5 ft.

The chemical mixing room is 37 feet by 34 feet, and a storeroom above of the same size. In this room is placed two setting tanks 12 x 8 x 6 in.; directly above is one circular tank, 5 feet diameter by 3 feet 6 inches deep, used for mixing the chemicals; two dry kilns two-storey high, 123 feet by 16 feet 6 inches wide, each heated by the "Common-Sense" system of radiation. The lower storey is filled with the lumber, placed on cars, and is fed by a fan 110 inches in diameter, connected to a condenser, 21 x 5 ft. 2 in. x 4 ft. 6 in. high; this condenser is filled with cold water radiators, which purify the air as t passes through same into heater 12 ft. 3 in. x 5 ft., 2 x 7 ft. 2 in. high; this heater contains 8,000 feet of 1 inch steam pipe, which heats the air to a given temperature, after which it is blown into the dry kiln at the extreme end and sucked out at the rear end by means of the fan, which makes a continuous circulation of air. Above the dry kilns is a room for storage of lumber, 125 feet by 33 feet. The office is 32 feet by 48 feet, and includes a test-room, in which the chemicals and solutions are tested for strength and impurities. A traverse table 35 feet wide by 10 feet traverses 137 feet and is worked by a steam winch. It is used for transferring the cars of lumber from the yard to the cylinder and from there to the dry kilns, this giving access to all tracks in the yard. The railway track from the Grand Trunk Railway enters the grounds about midway and passes through the centre of the building, connecting with the various rooms, so that the least amount of handling of lumber is avoided, ensuring economy and the smallest amount of damage to the material.

Mr. Percival W. St. George, Men. Inst., C.E., is at the head of the Electric Fireproofing Company, of Canada, Limited, and under his able management the electric process will no doubt soon receive in Canada the same degree of recognition that it has already received in the United States and England.

THE MILTON PRESSED BRICK CO., LIMITED

Works and Head Office: MILTON, ONT.

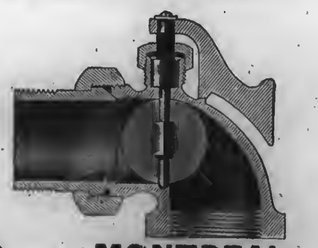
Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.



THE ROBERT MITCHELL CO., LIMITED - MONTREAL

Sold to the Trade Only. *Sole Licensees for the Dominion of Canada* *Send for Discounts.*

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited.

Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architect's Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. - In doing so, give both old and new address Notify the publishers of any irregularity in delivery.

RELATING TO PRESSURE OF AIR AND WATER.

It appears that the relations of pressure to distance in the forcing of water do not apply in the case of air, especially for long distances, although for short distances they may be taken as similar. Thus, if a certain head pressure be required to maintain an air current of a given volume and force through 1,000 feet, twice the head would not be sufficient for 2,000 feet. This is because of the increase in volume due to reduction in pressure, or loss of head, by the time the end of the first 1,000 feet has been reached. Consequently a greater pressure must be used to counteract this increased volume, in addition to the extra head required to maintain the force of the current beyond. The bulk of the pressure, however, is lost by leakage and by the bands and elbows of the tube, especially when the latter have too small a radius, the resistance or retarding effect increasing in some at present unknown proportion as the radius of the curve diminishes. In one case the loss of pressure, including leakage, was only two pounds of the initial 60 pounds required to transmit 875 cubic feet of air per minute through an eight inch pipe, 150 feet long. In another case, the driving of the Jeddo tunnel, at Ebervale, Pa., the loss was only 0.002 pound in transmitting air through a six inch tube a maximum distance of 10,800 feet, to drive two 3 1-4 inch drills. The volume of air required, however, for this purpose, 230 cubic feet per minute, was in small proportion to the size of the tube used. By careful consideration the transmission losses may be reduced to a minimum.—(R. Peel, Mine and Minerals, Pennsylvania, Vol. XX.)

If you are looking for a high grade Finish for Floors

Granitine Floor Finish

Is unsurpassed in Durability and Beauty of Finish for Natural Wood and Parquette Floors, Linoleums, Oil Cloth, Cork Matting, &c.

Its transparency reveals the grain of the wood, and its preserving qualities increase the life of the floor.

Its sanitary properties are highly commended, as it closes thoroughly the pores of the wood against disease germs, and permits the floor to be kept thoroughly clean.

It is easier applied, more durable, makes better finish than wax preparations, and is free from all unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks; nor does soap, mud or water destroy its fine appearance.

Manufactured only by

The Imperial Varnish & Color Co., Limited

TORONTO, ONTARIO, CANADA.

MACHINE-CUT vs. HAND-CUT STONE.

In the United States much controversy is now taking place as to the respective merits of machine-cut as against hand-cut stone. The advocates of hand-cutting declare that machine-cut stone when used for building purposes will not weather well. The surface is said to be shaken and stunned by the pressure of the heavy planing machine used. The very life and nature itself, it is said, is taken out of the stone by the planer. Small fillets are ground so that the fingers are almost able to press the edges off, and beads and other undercut members are stunned the whole length of the stone. It is urged also that there is yet another evil connected with the use of machinery for stone cutting, and that is the degeneration of the practical workman. If the use of machinery is further extended, it is urged that the new generation of artisans in the art of stone-cutting will know very little of the fundamental principles of their trade. All they will know is how to set in a mould for the planer, and how to joint the stone when finished. The advocates of machinery, on the other hand, declare that the use of machinery, if only by lessening the cost of production, has made the employment of stone possible where otherwise brick and cement, or some other substitute, would have been used. A planing machine will, it is contended, cut finer mouldings in true lines, either straight or circular, and leave the stone in a much better state to stand the effects of time than is possible by hand labor. Instances are cited in which stone of a kind easily split into thin slabs "bed way" has been so strained during hand labor as to be practically unsaleable; the same stone when machine-cut turning out excellent work. Be this as it may, it is certain that the use of machinery for stone cutting is largely on the increase in the United States, and is gradually spreading to this country. The cost of labor is the most important factor in the matter. It is the economic pressure thus brought along which will effect a revolution in older methods of doing work.

THE TORONTO INDUSTRIAL EXHIBITION.

The refusal of the property owners of Toronto to vote the money required for the erection of new Exhibition buildings, is a clear proof of their dissatisfaction with the management. That new buildings are necessary, few will deny, but new buildings alone are not sufficient to ensure the future development and success of the Exhibition. The management must also be improved. The Board of Directors should be re-organized, and the representation of the various interests made to properly correspond to their magnitude. As now constituted the larger representation is given to the bodies whose interest in and value to the Exhibition are the least. The Board is unwieldy and might with advantage be reduced in size. Some change seems also to be required in the personnel and methods of the immediate management if the Exhibition is to develop along broad lines and be successful. It has apparently reached its limit, if indeed it has not begun to retrograde, under the direction of the present managers. It must either go forward and increase in importance, or meet a speedy death. Forward should be the motto, and to that end everything that would stand in the way of progress be removed and the management brought thoroughly up to date. That should be the first step. When that is accomplished public confidence will be restored and the money for new buildings and other improvements will be forthcoming.

FIRE ESCAPES.

The manufacturers of fire escapes are enjoying a harvest of prosperity in consequence of the amendments to the Factory Act passed at the last session of the Ontario Legislature compelling all factory buildings to be equipped with proper escapes. The inspector estimates that in Toronto alone there are 300 factories requiring to be so equipped.

FIRE-PROOF GLASS WINDOWS THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

A HEATER

WITHOUT A JOINT

Is what we offer you in

THE PRESTON HOT WATER BOILER

The advantages of this feature in its construction are self-evident. There can be no leaks on account of bad packing, nor is there any opportunity given for expansion or contraction to open up joints. The water chamber is made in ONE SOLID CASTING, and so designed as to give a VERTICAL CIRCULATION. By making use of this NATURAL LAW, we greatly increase the efficiency of the heater.

A post card to us will bring our booklet with a full description.

The Site of the Victorian Statute.

THE Ontario government has rejected the proposal of the city council of Toronto that the proposed statue of her late Majesty, Queen Victoria, should be placed on the main approach to the Legislative Buildings, midway between the statue of the late Sir John Macdonald and the buildings. The government claim that this statue should occupy the foremost and most prominent position. This view will be generally admitted to be a reasonable and proper one. While it is perhaps an unusual thing to remove a prominent statue and place it in a less commanding situation, yet it would have appeared a graceful and reasonable act on the part of the city council to have consented to allow the statue of the greatest and best ruler the empire has ever had to supplant that of a colonial statesman, however great were his abilities and public services. Pity it is that the proposed Victoria Square opposite the new municipal buildings has not been secured by the city and is not ready to receive the Victoria statue.

Capital and Labor.

THE great combinations of capital and the aggressiveness of the unions of workmen in the United States, is bringing to a focus sooner than was expected the settlement of the relations that shall in future prevail between employer and employee. The most gigantic strike in history is now in progress between the steel workers and what is known as the United States Steel Trust. The employers are said to be losing a third of a million dollars per day, and the employees about half that sum. Upon the outcome of this great struggle will largely depend the conditions which are to govern, at least for a time, the relations of the combatants in the future. It seems impossible at present to forsee what the ultimate and permanent solution of the difficulty will be. It would seem, however, that there must either come a better understanding between employers and employees, by which regard will be shown for the interests of both, or the government must step in and compel the settlement of disputes by arbitration. In New South Wales, a compulsory arbitration law now prevails, and is said to be working satisfactorily. In Canada we have what are called Conciliation Laws, which provide means for the adjustment of disputes where both parties are willing to submit their case to arbitration. These laws appear to be a dead letter. The statement is made that in the present strike of trackmen on the C.P.R., which is a hindrance to public traffic, no request for arbitration has been made by either of the parties to the dispute. If the law is to be invoked, it must, to be of any service, be compulsory. It is most unfortunate that these disputes regarding wages and hours of labors should be allowed to block the wheels of industry in prosperous times, and hasten the return of commercial depression.

Decadence of the Exhibition.

In point of attendance the Pan-American Exhibition at Buffalo has thus far proved a failure. The holiday season, during which the largest attendance might reasonably be looked for, will soon have passed, yet the expected thousands have not put in an appearance, and in consequence it is rumored that the Exhibition may close at an earlier date than was intended. The fact is apparent that the Exhibition business has been overdone. The original idea of these large Exhibitions was to bring together the most improved devices and methods in manu-

facturing, as well as specimens of the natural products of the nations of the earth. So long as this was the prominent feature, and an interval of at least ten years was allowed between the Exhibitions, they were reasonably successful. In recent years, however, projects of this kind have become too numerous, while their educational value has seriously declined. The Exhibition of to-day is a huge bazaar and circus combined, depending for success not upon its ability to instruct, but to amuse and excite wonder. It is not surprising that agriculturists, inventors, manufacturers and artisans no longer think it worth the cost to exhibit, or the earnest worker in any department to travel long distances to visit modern shows. The city of St. Louis, where arrangements have been in progress for a year or more for an Exhibition on a large scale next year, has wisely taken warning by the failure at Buffalo, and postponed the event for at least three years. It is perfectly safe to assume that if with all its advantages of situtation, the Buffalo project has failed, St. Louis could not succeed in inducing northerners at least to exchange the cool breezes at the seaside, or by the great lakes, for her stifling atmosphere. She would do well to substitute for her proposed Exhibition a winter carnival. Canada's resources have only recently reached the point which would justify her in attempting to inaugurate a Dominion Exhibition. In view of the evident decline in public favor of such enterprises, the wisdom of embarking thereon now seems open to question.

Architectural Emotion.

Any student of literature can tell that the essentially modern phases of architecture, whether he likes them or not, are artificial, by merely reading what is written about them—if he can. The architecture generated by the arts and crafts movement in particular is given away at once by the young men who write about it. They are doctrinnaires and seek to persuade with words. Their style is uneasy. They feel the sense of the world to be obdurate, difficult to convince; and they wheedle and use adjectives. They contort their sentences so that the adjective comes first, and a superlative at that—"very pretty" is this, "very charming too" is that. They cannot let a plain statement stand by its own merits but seek to bolster it up with suggestion. It is not enough to say that a thing is of oak; they seek to commend it with the suggestion that it is "oak of sturdy British growth." It is not enough to suggest that a certain space will be convenient for pictures; we are offered the contemplation of "a few well chosen pictures." There is ultra refinement in this fewness. In the hammer marks on iron on the other hand we are asked to observe the interesting suggestion of sweat, which is not at all refined. When we come to the women's rooms, the inhabitants figure of course as "fair ladies," and the suggestion, made in one book, that we may imagine them talking about the Euphuists is remarkable. It would stick most fair ladies to say much about the Euphuists; but it is certainly suggestive that the authors of the book should have this sneaking regard for the most affected of England's many affectations. One is inclined to suspect that writers of this school would find themselves most at home talking art with the fair ladies. They are fond of certain words which come strangely from the mouth of a male man. "Cosy" is a favourite word, and "dainty" too we are sorry to say. It is to be feared that when these young men marry they will get wenches, though what the king needs is men. In America the theme is larger. It is not finish but creation they deal with, but the talk is not straight talk. Mr. Louis H. Sullivan's eloquence about the young man in architecture, to take a salient instance, is quite unnecessary. Abe Lincoln would have put the case in five minutes or less. Indeed there would be no need to invoke so great a mind. The work of talking about the "organic" and "functional" nature of true architecture and the "logic" of its expression is done; what we have to do now is to produce it, and if any talk will help us to that, it must be of the dry and scientific kind. There is too much emotion over architecture in the forward schools of the United States for one to believe that these producers have got down to a scientific basis. In the meantime Mr. Flagg, who represents the Frenchiness which represents classic taste in the United States, is cool and businesslike, and Mr. Reginald Blomfield, who in virtue of the new, handy edition of his Renaissance in England, may be taken to represent the classic school in England, is manly and dignified. One is convinced in reading the utterances of these gentlemen and others of the same class that, whether we like it or not, those who follow on in the old paths are practising a real profession of architecture.

L'Art Nouveau.

It is interesting to observe, as a corollary to the doctrine that "the old paths are the best," the divergence that is being made in France from the formalism that has hitherto been associated with French architecture. The newest minds are evidently tired of it, and are producing work which in feeling tends to the fantastic; though at present chiefly in detail. So far as that goes it is natural that freedom should begin with detail, as it is in the building up of design from fixed details that the formalism of the formal school arises. At present the new school of buildings ranges perfectly in general appearance with the prevailing Parisian type. It is only an inspection in detail that discovers the difference in feeling; but it gives an impression of wide difference, for the new detail is not only not formal but is formless. It has abandoned the Aristotelian basis of beginning, middle and end, and delights in forms that "grow" one from another, relying upon carving to get over difficulties of junction. This is nothing less, in its way, than a new French Revolution; a revulsion from one extreme to another. Unfortunately the opposite extreme from formalism is barbarism and L'Art Nouveau is nothing else; beautiful in refinement but unintellectual and promising nothing but reversion, because of disgust with itself. It seems to be the peculiarity of French logic that it can develop admirably, but cannot reform. The French idea of reform is reaction to the opposite extreme. It does not follow that the devotees of French architecture on this continent will follow the French in their reactionary vagaries, but it is decidedly worth while to observe these vagaries; and, before we accept the doctrine that French architecture is the only architecture, to note that there are some French architects who are tired of it.

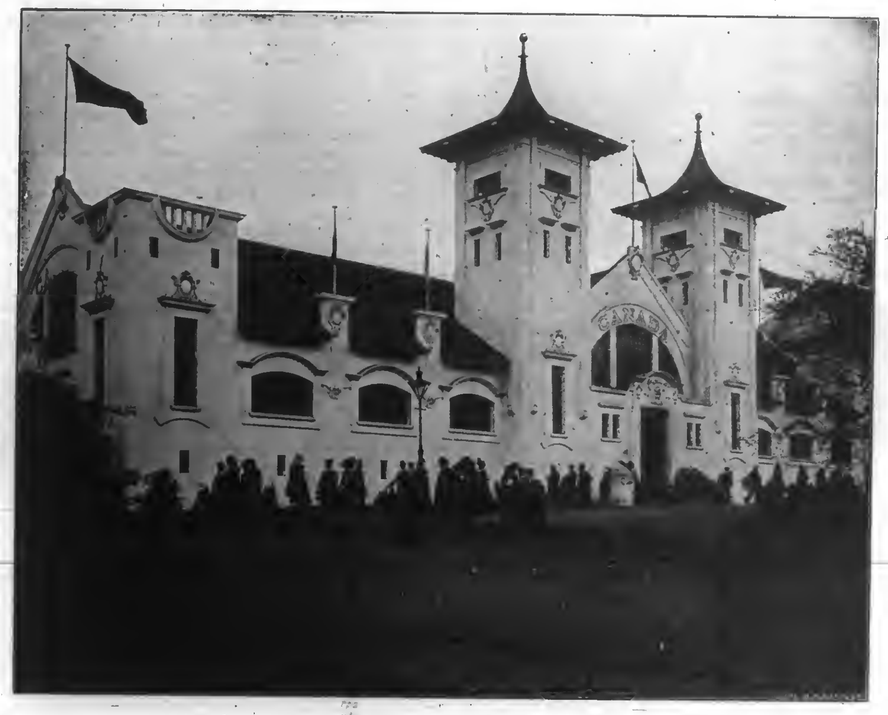
A large deposit of clay has been discovered near Little Current, Ont., which is pronounced by a German expert to be suitable for fire-clay and vitrified brick.

BY THE WAY.

For the first time since its erection twenty years ago, the spire of St. James Cathedral in Toronto is undergoing repairs and is being repainted. The work is being done by Messrs. A. B. Ormsby & Co., the steeplejacks being James Plumb and Frank Scully. The job is a hazardous one, the spire being upwards of 350 feet in height.

× × ×

It is not only Mark Twain's heathen Chinee whose ways are peculiar. In every community may be found people for whose peculiarities it is difficult to account. As a case in point, I may mention the circumstances connected with the buildings and plot of ground known as St. Patrick's Market, on Queen Street in the city of Toronto. This property was deeded to the city years ago for the purposes of a public market by one of the most wealthy and prominent citizens of that day.



Canadian Pavilion, Glasgow Exhibition.

For a number of years past two butchers have been the sole occupants of the building, which in reality has ceased to be a market, the business having been transferred to St. Andrews and St. Lawrence markets, situated respectively in the west and east ends of the city. Seeing that the property was no longer serving the purpose for which the donor intended it should be used, the city authorities proposed that it should be utilized as a public square, for which it is well adapted. Just here, however, the peculiarity of the administrators and assigns of the donor manifested itself. They declared that the property having been donated for a particular purpose, it must not be used for any other, and threatened that if it were so used, the rights of ownership would revert to the donor's estate.

× × ×

The interior of Osgoode Hall, Toronto, is being renovated and re-decorated in view of the approaching visit of the Duke of York.

× × ×

I learn from a contemporary that Miss Josephine W. Chapman, of Boston, a successful woman architect, will be the only representative of her sex at the Pan-American Exhibition, in Buffalo. Miss Chapman has erected a number of churches, business buildings, and residences. She employs none but men in her office, as she declares that women fail to give their undivided attention to the work, and at the most critical moment want to go home to make their clothes.

× × ×

A novel and expensive but not overwise method is said to have been chosen to determine the quality of the bricks produced by a large yard in the Western States. The proprietor and a brick mason contractor got into a discussion, and as the result a bet of $10,000 was made. The builder maintained that the brick would not sustain a column of 300 feet. He is to undertake the construction of a stack, and after it reaches a height that ordinary workmen refuse to continue on the structure, he will himself continue it up until something gives way. If it fall before it reaches 300 feet he wins: otherwise he loses. It is to be six and one-half bricks square at the base, with a square one-foot flue, up which the bricks are to be conveyed. The builder agrees to continue the stack until it falls, to be at the top when it gives way, and bets an additional $5000 that he will not be hurt in the collapse. The loser is to pay for the bricks.

BUILDING CONTRACTS.

The term building contract may be applied to any legally binding agreement which has for its subject matter or principal subject matter the erection of buildings or the execution of works of the nature of buildings, and, as generally used, it may be more particularly defined as an agreement by which one person or body of persons undertakes for a consideration to erect or construct for another buildings or other works of that nature.

The first necessity, in the case of such a contract, is of course that a site for the proposed buildings or works is to be provided, and as the usual occasion for a building contract is where the owner of a site desires to have it built upon, the term "building contract" is usually understood to import that the proposed buildings are to be erected upon the land of another for his use and benefit.

As the terms contract and agreement, as commonly used, have essentially the same legal significance of a legally binding agreement, that is to say an agreement enforceable by law, so there is not strictly speaking, any inherent or essential difference legally or grammatically between the terms building contract and building agreement, but in fact the former term has come to be used so as to import that the works to be done are to be done for the use and benefit of the owner of the land, whereas the term building agreement is usually confined to agreements providing for a grant to the builder of a lease of or other interest in the land upon completion of the building.

Although therefore either term may be applied to any agreement which provides for the erection of buildings, the term building contract naturally suggests to the experienced that the buildings are to be for the use and benefit of the building owner or employer, and consequently that the consideration is to be a money payment or something of the like nature, e.g., payment in shares of a company, whereas the term building agreement suggests that the builder is to acquire in consideration of his building a lease of or other interest in the land built upon. As illustrations, a simple instance of a building contract would be where—

> A., a builder, agrees with B., a landowner, to build him a house upon his land, in consideration of a lump sum to be paid on completion of the work.

And a similar instance of a building agreement would be where—

> A., a builder, agrees with B., a landowner, to build upon B.'s land in a specified manner, in consideration of B. granting to him a lease of the land and buildings.

The rent of such a lease is of course fixed at a sum considerably below the rack rent of the property as built upon, and the amount expended in buildings is in fact equivalent to a premium paid for having the property as built upon at a rent below the rack rent thereof. Although a contract to pull down a house comes within the Statute of Frauds as relating to an interest in land, and must be in writing, a contract to build a house does not.

In the case either of a building contract or building agreement, as above defined or distinguished, provisions will be found (1) on behalf of the landowner, (2) on behalf of the builder, and these are usually followed by provisions for the prevention or settlement of disputes which should be on behalf of both parties, but are in most cases found to be framed rather in the interest of the building owner or employer. The general object of the provisions on behalf of the building owner or employer is, putting it quite generally—

(a) That the buildings to be erected shall be of the desired nature and quality, and be completed within a specified time.

(b) That the builder shall not be entitled to his remuneration or consideration unless and until he has fulfilled his part of the bargain.

And the object of the provisions on behalf of the builder is—

> To put him into a position to claim his remuneration as soon as he has earned it under the stipulated terms.

Although these objects may be stated thus simply and shortly in a general way, the complicated nature of building operations and the many unforeseen occurrences which may intervene render numerous and elaborate precautions necessary for the prevention of disputes during the progress of, or after the completion, or (it may be) the previous abandonment of the works. The provisions embodying these precautions have now settled down into a number of well recognized clauses, the more important of which are to be found in any well-drawn building contract or agreement. These more important clauses it is proposed presently to consider in detail with special reference to the legal bearing and effect thereof and to certain judicial decisions thereon.

The subject of the present paper is building contracts in the ordinary sense as above distinguished, i.e., contracts for the erection of buildings or construction of works on the land of another person for the use and benefit of that other person. It is in the case of building contracts in this sense particularly, that the elaborate provisions to be presently considered are necessary in order to secure that the work shall be done in exact accordance with detailed requirements.

In the case of a building agreement, as an immediate lease or grant of the property is intended to be made to the builder, it is, as a rule, only necessary to provide that the buildings shall be sufficient to secure the intended rent and, perhaps, also to preserve the character of the neighborhood. For these purposes it is generally sufficient to provide that the buildings shall be of not less than a certain value and shall have a more or less uniform character. The builder himself having, or being about to acquire, an interest or estate in the property, may be relied upon to build so as to give the property a marketable value. Consequently it is not usually found necessary in building agreements to go into any great details as to the buildings to be erected.

When, however, buildings are to be for the use and benefit of the building owner, his first and foremost care will be that the agreement shall be framed so as to secure his getting what he wants in every detail, and to secure this is consequently the main object of the provisions of the contract on behalf of the employer.

Now if the buildings contemplated were nothing more than what Mr. Ruskin somewhere says is all that the ordinary British householder requires, viz., four brick walls and a drain pipe, the employer might possibly be able to decide for himself whether that desideratum were supplied, and the services of an architect or surveyor might be dispensed with. Pace Mr. Ruskin, however, and fortunately for the profession of architects, our needs and aspirations in the matter of building are seldom so simple, and, moreover, it is not only the demands of increasing wealth and luxury but the elaborate requirements of modern building acts which have to be met. Consequently building contracts are frequently required to provide for the proper execution of most extensive and costly works in accordance with most minute and detailed particulars. Hence the introduction into the contract or transaction of a third party in the person of the architect or surveyor of the building owner, whose duty it is to bring his expert knowledge to the assistance of the building owner as a guarantee that the work to be done shall be done in the way in which an expert knows it ought to be done.

One of the most important things to be considered is therefore the position of the architect or surveyor, both as regards the owner and the builder, and the nature of the authority, duties, rights and liabilities involved in that position.

Before proceeding to details, it is to be observed that, as in the case of all instruments where the salient provisions have settled down into recognized form this has been the result of a gradual growth, faults and deficiencies being rectified and supplied as experience has shown such rectification and supplement to be necessary. The case of conditions of sale will readily occur as an example of this growth or development. In preparing these, particular provisions to meet such particular case are required,

and are inserted by the draftsman as his skill and experience dictate, but beyond these special provisions there will be found a number of general forms which experience and the results of judicial decisions have shown to be necessary or expedient in every case, if disputes are to be avoided.

We come now to consider the general form which a building contract for the purposes and in the circumstances aforesaid has come to assume. In contracts for elaborate works, and especially in the kindred contracts usually known as engineering contracts, the instrument frequently commences with a series of definitions—

(a) of persons, e.g., building owner or employer, surveyor, engineer, clerk of works, etc.; and

(b) things, e.g., works, plant, drawings, schedule of prices, etc.

These, however, are rather matters of convenience and not of necessity, and need not be here considered.

For the reasons before indicated, viz., that the employer not usually being an expert, and so not being competent of himself to specify precisely what he requires, or to see that what is supplied is such, he will in the first place have employed an architect to prepare the plans and specifications for the proposed buildings, and the builder or contractor will be required to undertake to build them in accordance with such plans and specifications, and under the direction and to the satisfaction of the architect. The contract thus sets out by defining the work to be done, viz., that shown by the plans and specifications, and by providing a guarantee that it shall be properly done by requiring it to be done to the satisfaction of the building owner's architect or surveyor.

The question which naturally arises next is that as to the time for completion, and consequently the clause or clauses indicating the nature and extent of the work to be done is usually associated with or followed by provisions for securing completion within due time, and fixing the damages or penalties in default.

Next will naturally follow the question of the consideration or remuneration for the work with provisions as to the time, manner, and conditions of its payment. Then in order to prevent undue rigidity will follow provisions as to alterations and deviations.

It will then be found convenient to provide as far as possible for all matters or contingencies which, or the consequences of which might if left unprovided for, give rise to dispute or doubt, and of these the following may be here mentioned, namely:—Rectification of defects subsequently appearing, property in materials and plant, assignment and sub-letting of contract, bankruptcy of contractor, and lastly, there will be provisions for the prevention and settlement of disputes.

A convenient form of contract is—1st, To define or indicate the work to be done, the time for its completion and the nature and conditions of the consideration or remuneration, and then to schedule or otherwise annex the General Conditions of the Contract. These General Conditions are as above indicated frequently very numerous and exhaustive, and it is not within the scope of this paper to consider them in detail, but it is proposed to select a few of the more important which have been the subject of judicial decision, and to consider them with reference to those decisions.

Before proceeding to consider the first group of clauses, viz., those relating to the work to be done, the time for its completion, the payment or remuneration therefor, we may here consider the position of the architect—

(a) As regards the employer.

(b) As regards the builder.

(a) As regards the employer. The bargain between the architect and the employer for the preparation of the plans, etc., and his remuneration therefor, is of course a separate contract not concerning the builder, and as to this bargain three points only need be here considered—

(1) The remuneration.

(2) The ownership of the plans.

(3) Personal nature of the contract.

As to (1) it has been held in a case of Whipham v. Everitt, "Times," March 22nd, 1900, that though not legally binding on a building owner the charges of architects sanctioned by the R.I.B.A. are evidence of the reasonable nature of the architect's charges if in accordance with the schedule.

As to (2) If there is no special agreement as to ownership the employer is entitled to the plans when he has paid the architect his reasonable remuneration. See Ebby v. McGowan, "Times," Nov. 17th, 1870.

As to (3) The contract being personal, i.e., the personal skill of the particular architect being deemed to be relied on, the contract is dissolved by the architect's death. This is not so in the case of the builder, although it may be made so by express contract. Apart from stipulation to the contrary, if the builder dies, his representatives are bound to carry out his contract. Further, and this concerns the position of the architect as regards the builder also, he is the general agent of the employer for the purposes of the work he has to superintend (see Kimberley v. Vick. L. R. 13 Ev. 1), and as a result of this position of agency all dealings between the architect and the builders must be free from any suspicion of collusion, and if any collusion or secret dealing between the architect and the builder can be established, it will amount to a fraud on the employer, and entitle him to damages, or rescission of the contract. See Panama & South Pacific Telegraph Company v. India Rubber Telegraph Works Company. L. R. 10, Ch. 515.

Following the clause or clauses defining the work to be done as the main object of the contract, there usually follow a number of ancillary or subsidiary clauses indicating various preliminary and other matters and things to be attended to or done by the contractor, e.g.—

Giving of requisite notices.

Fencing.

Compliance with statutes.

Paying compensation for damage.

Indemnifying employer against risk.

The number and extent of these obligations of course largely depend on the nature and importance of the main works to be done, and the object is to throw upon the contractor the expense of all the preliminary and subsidiary matters which may be necessary to be done, or settled, in order that the main work may proceed to completion without any further expense to the employer than the stipulated cost. It is sometimes stipulated in the contract, that all materials be provided by the contractor at his own cost, but apart from such stipulation, a person who contracts to build a house impliedly undertakes to provide all necessary materials.

Resuming the question of the contents of the contract, we proceed to deal with the first group of clauses. The architect or surveyor is as we have seen the agent of the employer to see to the work on his behalf. In this capacity he is empowered—

(a) To inspect it, and, if necessary, to uncover and look into work for inspection.

(b) To require any inferior materials to be taken out and replaced by good, and any inferior or unskilful work to be redone or rectified.

If the architect's supervision is thorough and his powers to cause bad work to be made good are unflinchingly exercised, the probability is that a proper compliance with the contract on the part of the builder will thus be secured. But however careful the architect may be, defects of material or work may possibly be overlooked, and to meet this, the clause known as the Defects and Maintenance clause is inserted, providing for the rectification by the contractor of defects subsequently appearing in the work. The contractor, however, cannot reasonably be expected to rectify defects appearing at any time—however long—after completion, and consequently his liability under the defects and maintenance clause is always limited in time.

The clause is in fact in the nature of a guarantee that the work is done so as not to give way through defect in material or workmanship, and may be compared to a guarantee given with, say, a watch or a bicycle, and like such a guarantee is limited to a period in which such de-

fects (if existing) might reasonably be expected to become apparent.

Such is the nature of the usual provisions for the prevention and rectification of defects. But even apart from such provisions in the contract, if the work is inefficiently done, the owner may deduct from the contract price a reasonable sum in respect of defective work, and if payment has been made he may obtain damages for such defective work. See Davis and Hedges L. R. 6 Q. B. 187. And if the work is so improperly done as to be useless, he may decline to pay altogether.

As to time for commencement and completion. The contract usually provides that upon execution or at some fixed date the builder shall be entitled to enter on the land for the purpose only of executing the works, and so as not to create any tenancy or confer any further interest.

If the buildings are contracted to be finished within a certain time and are not so completed, the owner of course will have an action for damages for such breach of the contract. It is, however, usually deemed inexpedient to rely upon this remedy only, and consequently it is usually provided that in the event of non-completion by the stipulated day, a penalty is fixed by the contract of so much for every day beyond, until actual completion. These, unless they are excessive or unless there is something in the contract to show them to be included as penalties in the legal sense, are construed as liquidated damages. See Law v. Local Board of Redditch, L.R. (1892), 1 Q.B. 127.

For the protection of the builder, provisions are also usually inserted to meet the case of delay through unforeseen or unavoidable circumstances, e.g., stress of weather, strikes, disputes with neighbors, etc. In these cases a reasonable extension of time is provided to be allowed by the architect or surveyor. Another cause for extension of time which is usually provided for, though no doubt it would be allowed without express provision, is in the case of extra work being found to be and in fact required.

As to the Consideration or Remuneration. The simplest case is that where a lump sum is to be paid upon completion. Usually, however, at any rate in large contracts, the builder requires money as the work proceeds, and he therefore stipulates to be paid certain sums at certain stages. In both cases it is usually provided that the certificate of the architect shall be required as a condition precedent for payment, and this provision has given rise to various questions as to the conclusiveness of and necessity for the certificate. It has been decided that it is final and conclusive as between the builder and building owner, even if given without reasonable care. Stevenson v. Watson, L.R. 4 C.P.D., 148, and Rogers v. James, 1891, 8 "Times" Law Reports, 67.

This evidently puts great power into the hands of the architect, and much reliance must be placed upon professional honor. The builder has no remedy against him in case of mere negligence or merely unreasonable conduct. In this, however, as in all other matters, actual fraud will give a right to relief, consequently, if the certificate is withheld fraudulently and in collusion with the employer, the builder will have a right of action both against the architect for the fraud and against the employer for work done, even though the certificate be withheld.

It is, however, to be remembered that where the contract provides for payments in advance upon the certificate of the architect that so much work, or work of such and such value, has been done, these interim certificates are not final, and when the time for final payment and settlement comes they may be revised and readjusted, Tharsis Sulphur Co. v. McElroy, 3 App. Cases 1040.

As to the form of certificate; the contract may provide that it must be in writing or in some particular form, but in the absence of such provision it need not be in writing, and may be by word of mouth, and in any form amounting to a certificate, but it must be so expressed as to be in fact a certificate, and not as it were a mere admission.

In the recent cases of Chambers v. Goldthorpe and Restell v. Nye, 84 L.T., p. 444, it was held that the architect in giving his certificate was in the position of an arbitrator, and so not liable for negligence in so doing. Lord Justice Romer, however, dissented from this view, and considered that on giving his certificate the architect was acting simply as the agent of the building owner, and was consequently liable to him for negligence.

Deviations and extra work. It probably but seldom happens that in carrying out works of any extent they are carried out exactly in accordance with, and without any deviations from, the original plans. As the works proceed, either unforeseen difficulties present themselves, or the works themselves suggest improvements in the original design, or the employer alters his mind as to some idea or detail, acting on the principle that it is the unforeseen which happens, the draftsman takes care to provide for such contingencies as are above mentioned.

The two things to be provided for are—

(a) The extra remuneration for the extra work.

(b) The further time to be allowed.

(a) May be fixed either by reference to schedule of prices, or by the surveyor; and as to (b) the contract may stipulate that no further time be allowed, or it may provide that the architect or surveyor may allow such further time as he may think reasonable.

If no such provision is contained in the contract, and extra work is ordered, no penalty can be recovered for delay. See Dodd v. Churton, 1897, 1 Q.B., 562.

It may here be observed that where the contract provides that the architect may order extra work to be done, this does not give him authority to require deviations or alterations amounting to an alteration of the general plan as originally proposed, but only alterations in matter of detail. See Rex v. Peto, Younge and Jervis, 37.

The question frequently arises, What is extra work? and to this the answer is that it is work outside the contract as originally entered into. It is necessary for the execution of that work, although not specified it is not extra and must be done for the price originally stipulated for. See Sharpe v. San Paulo Railway Co., L.R. 8, Ch. 597.

Assignment and subletting of contract. In order to secure the services of a particular builder in whom the employer has confidence, it is usual to provide against subletting or assignment, and also to give power to the employer to determine the contract on the bankruptcy of the builder. In this case, in order to terminate the contract, the employer must do some act indicating his clear intention to exercise the power.

Property in plant and materials. In order to give better security for payments in advance, it is usual to provide that all materials and plant brought on the land shall be the property of the landowner. It would be insufficient merely to give power of seizure upon bankruptcy, for that would not prevail against the claim of the trustee—for this purpose it is necessary to vest the ownership in the employer. Moreover, apart from the question of security, it would obviously be inconvenient to risk the intrusion of the trustee upon the works, and the delay which might be caused by uncertainty as to what he could claim.

Of course when materials are built in upon the land they form part of it and belong to the landowner ipso facto. It is only in the case of loose materials and plant that the provisions against claims by the trustee in bankruptcy are necessary.

Arbitration and prevention of disputes. The contract usually concludes with a clause or clauses, the objects of which are—

(a) To prevent disputes.

(b) To settle disputes.

For the prevention of disputes, the architect or surveyor is sometimes empowered to decide finally, and without being arbitrator. This prevents his decision in the absence of fraud being called in question. But it has been held that where the architect has given to the employer an assurance that the cost shall not exceed a certain sum, he is not considered to be in such a position of impartiality as to render his decision unassailable, and if such facts be proved the builder might claim a greater amount. See Kemp v. Rose, 1 Giff, 258 and Kimberley v. Dick, L.R. 13, Eq. 1.

For the settlement of disputes which may arise, notwithstanding provision for their prevention, an Arbitration Clause in the usual form is generally inserted. It is in the interest of all parties, employer, builder, and architect, that the work should proceed smoothly. Every possible question therefore that is likely to arise should be provided for; hence it is of the utmost importance that building contracts should be very carefully drawn, and, architects, employers, and builders should endeavor to acquaint their legal advisers with any practical difficulty that may arise in a particular case, with a view to its being obviated in the future, whilst the lawyer's part is to carefully watch the course of judicial decisions bearing on the matter, and to frame his contracts from time to time in such a way that the dispute which gave rise to the case in question shall not arise in respect of the contract drawn by him.

Perfection in legal draftsmanship is, perhaps, not possible of attainment, but, if the course I have suggested be taken, we may hope in time and by experience to produce a form of building contract as nearly perfect as it is possible for such contract to be.—H. H. Richardson, solicitor, in the Architects' Magazine.

THE MANUFACTURERS' ARCH COMPETITION.

In the competition instituted by the Canadian Manufacturers' Association for designs for an arch to be erected in Queen's Avenue, Toronto, for the approaching visit of the Duke of York, there were twenty-three competitors representing architectural designers as well as designers engaged in various other occupations. The latter, as might be expected, were at a disadvantage owing to their lack of knowledge of construction. The choice was, therefore, narrowed down to eight or ten designs. The Committee appointed to judge the designs after having spent considerable time in discussion upon their merits, awarded the prizes as follows:—First prize, Mr. C. J. Gibson, architect; Toronto; second prize, Mr. Henry Simpson, architect, Toronto; third prize, Mr. W. P. Witton, architect, Hamilton. These three designs are reproduced in the illustration pages of this number.

Mr. Gibson's design, which has been chosen as the one to be erected, will be 150 feet in height from roadway to top of main flag pole. The arch proper will be 45 feet high and 44 feet wide at the base, the total width from side to side being 100 feet. The framework of the structure will be wood with a covering of staff. The keystone of the arch will represent the Union Jack, with beaver at the base and crown above. On top will be placed an immense globe, with the figure of Canada prominent. The panel at the basis of the fountains and abutments will represent the history of manufacturing in Toronto. The fountains will be decorated with indigenous flora, symbolizing the many lakes and rivers of Canada. All the architectural ornaments will be conventionalized from Canadian floral forms. The voussoirs will contain plants symbolizing various forms of manufacturing. The arch will be strongly colored and richly decorated with flags of all the British possessions and at night will be brilliantly illuminated with electric lights. The coat of arms of the Duke of Cornwall and York will be prominent at each side of the entrance. The approach to the arch will be lined with a colonnade of tall flag-staffs.

The design submitted by Mr. Simpson was placed second and awarded the prize of $100. It shows an arch on all four sides, square in plan, of a purely classic treatment, with Ionic columns, and profusely decorated with festoons of evergreen leaves, the electric lights following the lines of the evergreen, entwining around the columns, carried across and around the pediments, drooping centre to outer flag poles and otherwise. The south side of the arch is approached from College street by a line of Venetian masts on each side of roadway connected with evergreen festoons, electric lights, etc. Each flag-pole is decorated with flags and shield, etc. The structure proper is designed to be built of staff painted in rich, warm colors surmounted by a rich green dome. The architect in planning his design has given careful consideration to the silouette, the general effect and its suitableness to such a festive occasion as the reception to the Duke and Duchess of York shall be.

Mr. Witton's design shows the decoration of the street by a series of masts draped between with bunting and finishing with a triumphal arch at the south end. The arch and the bases of masts to be of staff. The tenders received indicated that the work would cost about $5,350.00.

AWARDS TO CANADIAN ARTISTS.

Among the awards announced by jury for the division of fine arts of the Pan-American Exhibition are the following to Canadian artists:—

Group 1 (136), class 577, paintings in oil, water color, pastal, and other recognized mediums, miniatures, cartoons:

Gold medals—William Brymner, Robert Harris, Homer Watson, W. Blair Bruce.

Silver medals—E. Dyonnet, E. Wyly Grier, John Hammond, Laura Muntz, James Wilson Morrice.

Bronze medals—Maurice Cullen, William Cruikshank, Edmond Morris, A. D. Patterson, J. St. Charles.

Honorable mention—M. A. Bell, F. M. Bell-Smith, F. H. Brigden, Florence Carlyle, J. W. L. Forster, J. L. Graham, Robert F. Gagen, F. McGillivray Knowles, C. M. Manly, Mary H. Reid, S. Strickland Tully, Paul Wickson.

Group 2 (137), class 578, sculpture, including medals and cameos:

Silver medal—W. S. Alward.

Not in competition as member of Jury of Awards.

Group 1 (136), class 577, paintings in oil, water colors, pastel, and other recognized mediums, miniatures, cartoons—George A. Reid.

The awards in the section of architecture have not yet been made owing to the difficulty in bringing the jury together in Buffalo.

A PLEA FOR ATTRACTIVE FACTORY BUILDINGS.

Mr. J. P. Murray, a prominent member of the Canadian Manufacturers' Asssociation, states that the doctrine that factory buildings may and should be made architecturally attractive, is being impressed upon the attention of the members of that important organization. We imagine that we are primarily indebted to Mr. Murray himself for this commendable step. He has long been an ardent and useful advocate of the wisdom of uniting utility with beauty. The factories of the Sunlight Soap Co. on Eastern Avenue, and the City Dairy Co. on Spadina Avenue, Toronto, are an evidence that factory buildings need not necessarily be coarse and ugly structures, but on the contrary that they may be endowed with features of beauty and interest.

Much unfavorable comment has resulted from the announcement in the press that the contract for redecorating the residence of the Governor-General at Ottawa, has been awarded to a New York firm. The opinion prevails that this work could have been as successfully done by Canadian artists and workmen.

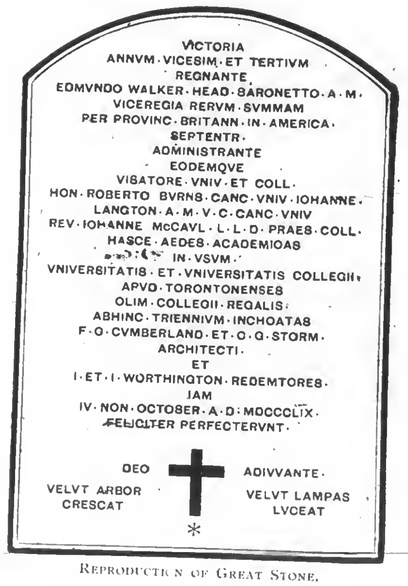
At a congress of architects recently held in Dijon, the conlusion was arrived at that carbonate of lead should not be adopted in house painting. The opinion of the other architectural societies is to be sought in order to ascertain whether a substitute cannot be discovered. The material has been often condemned, but still white lead is most generally employed not only as a pigment but as a base for other colors.

China and Japan are now utilizing their materials for cement, and they have the advantage of being able to deliver supplies in California thirty days after the order has been received. The Irish laborers who are employed in connection with the shipping have an aversion to carrying Chinese goods, but they are easily conciliated by having green labels placed on the bags, and by labeling the cement as "Portland."

THE STORY OF A UNIVERSITY BUILDING.*

Memory has environed many an ancient ruin with the annals of its past, clothing the hoary and mouldering stones with life as does the ivy which hides the progress of its decay. When admiring the magnificent buildings of early centuries the spectator finds not a little of his interest fanned by learning the history of the men who conceived and built them, and in tracing the soul-marks which these men left upon them and the ideas which they endeavored to express. Often the very times and moving impulses of successive periods may be followed in the great Cathedral and Monastic buildings where piety and wealth have age after age each added its quota to the original edifice—the rude, unchiselled solid arch, the massive walls and narrow crenelated windows, the simple rounded columns, whose beauty is in their strength, pass onward into more moulded forms and more sun-lit space. Asylum from pursuit gives way to consciousness of freedom, and decoration tells of immunity from ruthless invading hands. So studied, they become more than mere masses of architectural interest.

In a new land like ours where buildings grow apace and forest trees are lone records of a previous century, it is well to note whatever we can of the motives which moved



REPRODUCTION OF GREAT STONE.

the builders of our earlier days, and so attach the memory of their intentions to the visible products of their skill. In such spirit this record is made.

We have in Canada no single building in whose walls the course of history may be traced, yet in the buildings of Toronto University we have the reminiscence of an eventful period in the history of the University itself, and an untrammelled effort to create and preserve the ideals which impelled its founders.

On a great stone set in the inner walls on the second story of the main tower, and which, fortunately, was not destroyed by the conflagration of 1890, is preserved the names of those under whom the building was erected. This stone is reproduced herewith in such imitation as is possible with type. The Latin inscription was probably the work of the erudite Rev. Dr. McCaul, then president of the college, and a world-known authority on ancient inscriptions.

The Governor-General of Canada at the time, and by virtue of his office, Visitor of the University, was Sir Edmund Head, a man of cultivated taste and high scholarly attainments. He had at one time himself been a professor at Oxford, and was ardently imbued with the desire of aiding in the foundation of a broad laid and permanent University in the country to which he had but recently come in 1854. His views were clearly expressed in a speech delivered by him in Quebec when he said, "an endowment such as that enjoyed by the University of Toronto is a most valuable element in the future progress of this country. Such an endowment once lost or diverted to other purposes is not easily recovered."

The Latinized names of the Chancellor and Vice-Chancellor and of the Architects and Contractors are also recorded in the inscription.

Mr. F. W. Cumberland, who had been a student under Sir Chas. Barry, had, after coming to Toronto in 1847, engaged in the practice of his profession as an architect. The present St. James' Cathedral commenced in 1850, to replace its predecessors which had been destroyed by fire, is one of the early examples of his work. In the original design of this building, a choir of ample proportions was proposed between the Apse and the main body of the Church. But this for motives of economy was omitted from the construction, and the Apse moved forward to abutt, as it now does, upon the great arches of the Nave. Even in its present form the Church is still considered an excellent example of applied Perpendicular Gothic. The spire, which was subsequently completed in accordance with his designs, forms one of the graceful landmarks of the city. This and the severely classic and pure Ionic form of the present Receiver-General's office, were executed while Mr. Thomas Ridout was a member of the firm. In 1851 he was nominated a corresponding member of the Royal Institute of British Architects, and subsequently associating with himself Mr. W. G. Storm, of Toronto. The Normal School and the central part of Osgoode Hall are after works of the new firm.

Here it will be well to note the condition of University matters in Upper Canada precedent to the erection of the University buildings.

King's College, created in 1826, the first endowed University of the Province, had been passing through its phases of change and strife. In 1849 its name had been changed to that of the University of Toronto. Since its original inception other universities had been established in the Province and finally, in 1853, to meet the changed conditions, a division was made of the duties in higher education to be performed by the Provincial University. University College was then first created, to be a teaching Faculty in Arts, having a separate governing body, and a distinct entity as a purely College foundation.

To the University of Toronto, the "abstract entity," was transferred all the University powers of the original creation, such as the holding of examinations, the granting of degrees and the regulation of academic standards. Provision was made in the Act of 1853 for the Federation with this Degree-conferring University of the then existing Universities of the Province, such as Victoria, Trinity, and Queen's, and of such other teaching Colleges as should be qualified to be joined. These separate units of University energy and education, each retaining its own particular individuality, would, it was hoped, together with University College, in time be joined in union with the central University which was to become a part and the elevated representation of them all. Such was the ideal of the men of that day.

For many years the abode of the Provincial University had been the shuttlecock of fortune. Five times in seven years had its quarters been changed. Turned out of the King's College buildings which it had constructed, it was transferred to the Old Parliament buildings on Front St., thence, on return of the Government to Toronto, back again to King's College. Later, it was again moved to the old Medical School whose site is now occupied by the Biological building.

Nor was it more happy in the possession of the remaining lands which had been granted for its use. Under the Reconstruction Act of 1853, the Government had taken power to appropriate out of the University property which had been granted for Collegiate purposes at the head of College Ave., "sites for a Government House, a Parliament House, and Buildings for the accommodation of the Public Departments." The necessity for securing its lands and obtaining a permanent home was, therefore, deeply but quietly engaging the thoughts of the University authorities.

*Reprinted by permission from the Canadian Magazine.

A solution of the division of the property was at length arrived at and when it was determined to erect new buildings Mr. Cumberland, who had been a member of the Senate since 1853, resigned his position and was appointed architect to the University, Mr. Storm being then a member of the firm. At the instance of the Senate Mr. Cumberland in 1855 again visited Great Britain and the Continent, and for nearly a year made special study of University and other architegural buildings and of their adaptation to our means and climate.

The finished conception both in the massing of the grand yet reposeful outlines of the exterior and the elaborated parts of the University buildings are the results of his wide investigations and of the mass of detailed studies which he made in preparing for what he considered a work worthy of the highest art. The preliminary plans were then prepared, and quietly in the presence of a few members of the building committee, on the morning of the 4th October, 1856, the first stone was laid, and thereafter the building grew.

It was the expressed intention of Sir Edmund Head, Vice-Chancellor Langton and the active members of the building committee that the edifice should be one which should cellence around which the aspirations of the new University just created might in future days cluster, and so, under the influence of its outward home, grow in artistic and intellectual strength.

GROUP OF CARVERS—FROM A PHOTOGRAPH TAKEN AT THE TIME OF THE ERECTION OF THE MAIN BUILDING OF THE UNIVERSITY OF TORONTO. IN THE CENTRE OF THE GROUP, BAREHEADED, IS ZOLIKOFFER THE MASTER SCULPTOR, WHO WAS BROUGHT WITH HIS ASSISTANTS FROM GERMANY TO DO THIS WORK. THE CARVINGS ARE SOME OF THE ENRICHMENTS OF THE CONVOCATION STAIRWAY.

Surplus University revenues of considerable amount had been accumulated, so there were ample means on hand with which to proceed. Sir Edmund Head took a daily interest in the structure; his personal instructions were, as told to the writer: "Spend all the available endowment, or as much of it as you well can, for, if you don't, some people will some day come along and want to fritter it away for other than University purposes. We will anchor the endowment for the University by spending it on its buildings."

Sir Edmund found in Mr. Cumberland an architect after his own heart. Under these influences the edifice grew not only as a collection of rooms for educational purposes, but as a permanent example of noble architecture. While the nature of modern requirements in light and space in the interior modified in some degree the outer plan, yet the Norman-Gothic style of the design remained dominant in the architectural key of the exterior, and in the finish of all the details of its parts. Although adapted to modern uses the composition is one of absolute architectural values, and is the result of intensest study.

As in a landscape framed by nature all the surrounding ranges seem by intuitive relation to lead to the summit height, so in the University buildings the eye is imperceptibly, yet by carefully planned steps led up to the dominant feature of the design, the great Norman Tower. While apparent balance is maintained in the wings and on either side of the principal southern façade, yet there is no commonplace repetition. In many buildings one wing is but the reproduction of the other, a repetition on either hand of the same construction; but in this by tower or by gable, by minaret or change in form or grouping of classic windows, an artistic variance is introduced, while the relative proportion is preserved. None of these varintions are obtrusive, none abstract the eye from the general design, each while revealing its own individuality is honorably subordinate to the general duty of faithful service in promoting and leading to the central glory of the whole. From whatever point of view the edifice be approached, this lesson of highest ideal is declared in the storied stone. Such was the general scheme.

In carrying out the details of the building the utmost fidelity was maintained to the best examples of the ancient style.

In the old building, the major portion of which has been preserved, there were no two carvings the same, no two capitals, no columns, no enrichments repeated. Each detail is a separate study, and the wealth of invention and the art of workman and architect found in the mediaeval buildings is equally here to be found. Skilled art-carvers were collected, the master sculptor and his chief assistants being brought from Germany. A special study of the excellence with which they executed their work and produced the designs of the architects will serve in this one building to give an education obtainable only by much difficult and distant wandering.

One glory of the old interior, the stone stairway with its antique roof near the Convocation Hall, has unfortunately passed away with the conflagration in the building.

Here was lavished a very wealth of carving which would have been worthy a pilgrimage to visit. The enrichments were in Caen stone wherein bird forms interlaced with foliage executed in minutest detail were introduced, and examples of the grotesque carvings prevalent to the style produced both in wood and stone. Many other examples of worthy carvings are still extant in the

remaining part of the building, but this Convocation stairway was one of the architect's delights.

It was a happy fortune that the exterior of the building, and particularly the magnificent central door of the Great Tower, came through the flames unharmed. While every part of the exterior stone had received its due share of artistic enrichment, on this has been concentrated the full rendering of the best ancient art.

The East door, in rich but simple outlines, leading to where was then the Convocation and Examination Hall, speaks of severity and accurate learning; the little Western door, hidden behind its pillared cloister enriched with grotesque carvings, whispers of academic quietude and privacy, but the noble Norman portal beneath the massive Norman keep dominates in majesty and design all other openings, and fitly acclaims its place as the principal entrance to an enduring and classic Hall of learning.

Conceived with such ideas and intentions, and executed in such manner, it can easily be understood that the original estimates for the construction of the buildings were far exceeded. To Mr. Cumberland had come the share of planning and designing, of creating the composition, the selection and invention of the adornments of the Norman style; with Mr. Storm was the execution of the works and the honorable care of construction. Both lavished their best in performing the duties of their profession.

The authorities, however, declined to pay them for the extra services they had given, due to the increased character of the work and of the wealth of artistic detail which had been added to it. Hurt at this want of appreciation of artistic effort, and affronted by the refusal of his claim, amounting to between five and six thousand dollars, a large amount of which had been expended in preparing full-sized drawings for the carvings, Mr. Cumberland abandoned the profession of architecture and betook himself to railwaying, in which he had at intervals been interested, and the University building was the last architectural work in which he engaged. Mr. Storm continued in the practice of his profession, Victoria College, built in 1892, being one of the principal works which engaged his subsequent attention.

In comparing the University buildings with other edifices which have been executed in this city, it is to be remembered that since then the utilitarian has largely overmastered the artistic. The cost of construction is more thought of than the creation of architectural expression, and architects are not encouraged to devote to architectural effect so large a portion of the expenditure of construction nor given scope to develop the artistic side of their profession. When they are granted this liberty then abiding and adequate results may be obtained.

In the buildings of the University an endeavor was made to adapt the best mediaeval Art and to represent academic ideas in visible form. Speaking at the celebration held on the occasion of the placing of the copestone on the Tower, on 4th October, 1858, Sir Edmund Head "congratulated the architect upon being the first to introduce this style of building upon the Continent, there being, so far as he was aware, no instance of Norman or Romanesque style of architecture in America. He believed the style capable of producing many useful results. It was the adaptation to modern purposes and uses of the community now existing of the style of an early day. It was the history of modern civilization."

That some success has been obtained would seem to be inferred from the fact that the buildings, although shorn by fire of some of their early adornments, much of which was however faithfully restored, yet continue to be a source of study to those who are architecturally and artistically inclined and after fifty years are still regarded as one of the finest examples of applied Gothic architecture on the Northern Continent.

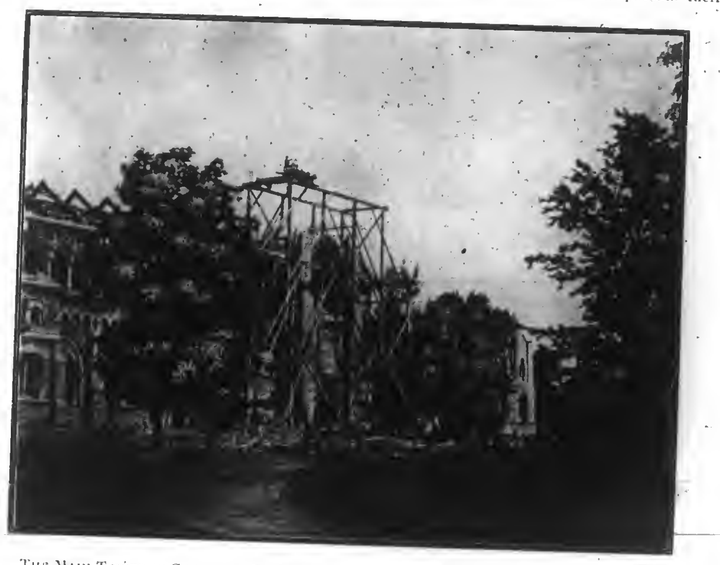
Whatever they may be to the general public, they were intended to stand as a lesson and an inspiration to all interested in academic culture. Not by rigid repetition nor cold uniformity are the several parts massed together, but as the associated Colleges, each governed by its own methods and contributing its special school of culture, would join in harmony to strengthen and elevate the value of University Education, so the several groups of the buildings, each separate in treatment and perfect in itself, were blended in union to add glory and support to the general design.

As the Great Tower concentrated the proportions of these, so were the colleges to found the character of their Federated University, each giving of its best to lead upward in the noble cause.

To the students who enter its portals their Alma Mater speaks in no uncertain way. As they are the living stones which build her reputation, so her habitation expresses what they themselves should be. Every stone is true; no false stones or veneer, but true stones built deep into the wall, each being what it looks, and truly doing its ungrudging share of duty. Anyone who saw the massive blocks which were built into its walls will understand how, when the fire swept through it, the building bore the stress and the mighty Tower, though shorn of its interior, stood scathed, but firm. It was built as builded the Norman builders of old.

And decorated stones there are, like students who win renown. Under the cornices around the whole building are series of carved stones and on all the capitals and enrichments, yet no two the same; even the wooden capitals of the cloister of the inner quadrangle are each cut in different forms, yet all these special stones are moulded according to the same architectural school, fit examples of the pervaging period of the design. Individuality of manhood is not lost in the student, from whatever college he may come, but is marked in scholarly eminence, as are the carved stones in the walls of his University.

May it not be that the hopes of the period they mark may some day be realized and that like the great buildings of older lands, those of Toronto University may become cherished memorials of formative days, an inspiration to the men who come within their influence, and to works of value in the progress of our country.



THE MAIN TOWER IN COURSE OF ERECTION—THIS PHOTOGRAPH SHOWS THE TREES WHICH WERE CAREFULLY LEFT IN POSITION AND PRESERVED TO ADD TO THE APPEARANCE OF THE BUILDING. ALL THESE HAVE SINCE BEEN REMOVED.

BRITISH COLUMBIA LETTERS.

No. VII.

The Second Annual Exhibition of the Arts and Crafts Association was held in the Fairfield Block, from June 28th to July 5th, and though the collection of works of art was probably the best ever brought together in the province, so little interest was taken in the show by the public that it was, financially, a complete failure. In a town of 25,000 inhabitants a collection of paintings, including examples by George Moreland, Gerard Dow, George Fripp, Albert Hartland, Knowles, Ferrier and others of greater and lesser note, such a collection remaining open to the public for seven days, attracted an average attendance of 30 per diem. A nigger minstrel show would have drawn five hundred.

However, if one cannot congratulate the people of Vancouver on their powers of discernment in matters of taste, the officers of the Association must feel that the want of success of the exhibition was certainly not due to any lack of energy or enthusiasm on their part.

The numbers of and the interest in the works by local members was not equal to the last year's exhibition. Mrs. Marcus Lucas, whose clever painting and well chosen subjects were a notable feature in the show of 1900, was represented by but a few oil paintings surrounded by a draping of black and violet, the Association having been robbed by the Destroyer of this admirable artist and enthusiastic supporter but a short while ago. Mrs. Marcus Lucas will long be remembered and her loss deeply regretted by all lovers of art in this city. Mrs. Ellis' charming work on china was this year represented by but half a dozen pieces, of which we most admired two plates designed by Mr. Jas. Bloomfield. The Misses McLung having left Vancouver just before the opening of the exhibition, were both unrepresented, as also was Miss Marstrand, whose work in black and white was greatly missed, as well as her quiet but effective assistance on committee. Others who contributed last season have withdrawn, and consequently the Asscciation has had some difficulty in maintaining the local character of the exhibition. Still, Mrs. Balfour Kerr and Mrs. Lionel Williams were well represented in oil colors, and Messrs. DeForest and Ferris each sent a number of characteristic works in the same medium. Mr. Tom Fripp's "Venetians Threading Beads" is a new departure for him. In water colors, Mr. Ferris showed but four small drawings, while in this class the only other exhibitor was Mr. Tom Fripp, whose large drawing "Chill October" is the most important work that artist has shown here. His sketches "Venice" and "Burrard's Inlet," are full of light and atmosphere. In black and white, the same artist was the sole contributor, principally portrait studios in chalk or pencil. In china Mrs. Ellis, Mrs. Harry Burrows, Miss Ede (who gained Mrs. R. B. Ellis' special prize), and Miss Drainie showed some beautiful work. Miss Drainie's fish set, accompanied by the clever designs prepared for this set by Mr. Jas. Bloomfield, is an exceptionally charming piece of keramic ware. It is good to see that conventional design is receiving much greater attention, though there is still far too much of the mere representation of fruit and flowers with little if any attempt at decorative treatment.

A screen of water colour sketches by Mr. Francis Caulfield was of very great interest, comprising a wonderfully wide range of subject: "Richmond on Thames" is a distinctly clever piece of difficult perspective; "Hampton Court" is scarcely less so; "The Chestnut Avenue, Bushy Park," is well contrasted with "An Orange Grove, California." Mr. Caulfield again showed his delightful piece of carving in oak, a panel entitled "Dolphins Plunging Through Water," which is full of movement and vigor.

Mrs. Balfour Kerr and Mrs. Lionel Williams had a screen of embroidery, some of it extremely well designed and executed. It seems somewhat strange that there should be so very few contributors in this most interesting class of work.

Mr. Harry Burrows chip carving and burnt work was most favorably commented upon, his cabinet and an occasional table being the most excellent examples of his skill. Mrs. Burrows also showed some pretty calfskin cushions with pyrographic decoration. Messrs. Henry Bloomfield & Sons were represented by a couple of stained glass windows, one, of which the motif is gold fish and kelp, being as fine a piece of color and drawing in lead and glass as we have seen for a long time. Mr. Jas. Bloomfield also showed some cartoons and a folio of delightful schemes in leaded glass; judging from some of these it would appear that this artist is finding more and more to interest him in mosaic treatment, some of the designs being for absolute mosaic in glass and lead without painting.

The only architectural drawings on the walls were by Mr. R. M. Fripp, F.R.I.B.A., Vice-president of the Association, among them being three drawings lately exhibited in the Royal Canadian Academy or Arts Exhibition at Toronto: a design for oak sedilia to be built for St. James' Church; a fumigated oak sideboard and drawing room fitments also in fumigated oak, designed and executed for Mrs. D. G. Marshall, also designed by Mr. Fripp, were the only designs for furniture in this exhibition of arts and crafts.

The newly constituted Manual School had an interesting exhibit kindly loaned and arranged by Mr. T. Northrop, the principal.

The school children's competition did not show any decided advance over last year's form. Many of the drawings were obviously not from Nature, and in some classes there were no entries and some of these classes will probably be dropped next year. The following is the list of prize winners:—

Class A.—Sec. 1.—Edith Wright; Sec. 2.—Vivian Garvey; Sec. 3.—Rhoda Macrae.

Class B.—Sec. 1.—Maude Tregent; Sec. 2.—Erma. Hurst; Sec. 3.—Violet Henderson; Sec. 4.—Hester Barker; Sec. 5.—Mabel Tregent; Sec. 6.—Harold Ferguson.

Class No. 5.—Ross Fraser.

For pupils of the MacDonald Manual Training School:—No. 1.—Gordon Johnson; No. 2.—Ernest Macready; No. 3.—C. M. Braden.

A special prize for landscape drawing in pencil was awarded to Jessie MacDonald and Mrs. R. R. Ellis' prize for painted china, open to students only, was won by Miss Ede, with some particularly well drawn conventional designs in extremely pleasing color.

The loan exhibition was a very varied and interesting collection of oil and water color paintings, pastels, engravings, Sevres china, curios from every quarter of the globe, and a few but excellent examples of ancient and modern printing. "Pigs Feeding," by Geo. Moreland, "The Poultry Vendor," by Gerrard Dow, "The Whist Party," a reputed G. Dow, and "Tam O'Shanter" by David Ferrier, were a singularly fine group of oils. A very slight portrait sketch by John Ruskin was kindly lent by the subject of the sketch, Mrs. G. Edwards. A pair of very beautiful seascapes in pastel by Holden (lent by Dr. Mostyn Hoops), were greatly admired, the broken water and driven clouds showing vigor in their handling, impression of wind and sunshine, cloud and shadow being rendered with fine skill. A large water color drawing by Albert Hartland (lent by W. E. Chapman) was a good example of this painter's later work; the subject "Lake Killarney," is world famous and the soft atmospheric effects were charmingly rendered. Two very early examples of Hartland's were interesting, but did not show much of the breadth and skill of the larger work. Three lovely little drawings by the late Geo. A. Fripp, R. W. S., were lent by his son and pupil, Mr. Tom Fripp; of these "Norfolk Broads" was the most finished and characteristic of this master of the grand old school of water color painting, but the others were also so delightfully warm and luminous it is hard to dogmatise as to their relative value. Colonel Falk Warren lent a collection of prints, one of them, an undoubted Al Trecht Drer. A number of Wouverman's and other Dutch draughtsmen, together with some excellent steel engravings (most unfortunately robbed of their margins), made up a deeply interesting and highly instructive set. The association was also indebted to Mrs. Marstrand for a capital pen and ink drawing by Prof. Marstrand and several oil paintings by Danish artists, of which we preferred "Mentone" by Prof. Zacho.

A gothic blackletter Bible (Portuguese) dated Lisbon, 1526, and printed by Huysman, (lent by Mrs. MacLagan), and some good Royeroft and Mosher books formed a small but select company in a glass case.

Seypores, Binares, Moorish and Japanese metal work, Fijian clubs and Karu bowls; Cloisonne placques and vases: Tibetan, Korean, Indian, Afghan, Samoan weapons; Lucknow silverware, Chinese embroidery, Zulu bangles, Japanese armor; Kaffir pipes, girdles, necklets and Australian Blacks boomerangs and spears; paddles from the Solomon Islands, New Guinea drums, Suivash basket work, elk teeth girdlers, mud pieces and many other odd, quaint and curious things, each and every one of which betrayed skill in their production, art in their decoration, often amounting to art of high rank, all these things carefully marked and catalogued, displayed on walls, benches and screens, wanted but one thing to make the exhibition a complete success and that one thing, intelligent appreciation, the public of Vancouver did not give, probably because they have it not to spare.

STUDENTS' DEPARTMENT.

ARCHITECTURAL EDUCATION.

At the recent convention of the Architectural League of America, short papers were presented by representatives of the various clubs composing the league, treating of different phases of the subject of the proper education of architects, which had previously been assigned to each club for consideration. For the Toronto Architectural Eighteen Club, Mr. Wm. Rae contributed the following as the views of the club on the questions submitted to it, which were :

"How much mathematical and engineering training should an architect have ?"

"Should design and construction be separated so as to train specialists in each of these lines ?"

(A). An architect should have as much mathematical and engineering training as will enable him to solve, by means of formulas derived from the experimental research of scientific experts, every problem the erection of a modern building may involve in the safe and economical use of the materials of its construction, including steel construction, heating, lighting, ventilation and sanitation.

In considering this question we have borne in mind the difference between education and merely a knowledge of the expedients of modern practice, for these expedients vary so much in different localities and change so from time to time, so many men devising their own, and ever learning fresh ones, that we think no rule may be laid down concerning them.

The use of formulas and tables thus derived we think one of the most justifiable expedients of modern practice.

The architect's work is the harmonious association of all the crafts, which harmony can only be considered complete when the possibilities of each craft in relation to the whole are perfectly developed, and to do this a knowledge of the nature and functions of every material used is necessary.

(B). Design and construction should not be separated, so as to train specialists in each of these lines, because a specialist is one who, in addition to the ordinary knowledge of his craft, acquires a special knowledge of one line, not one who has acquired a knowledge of one line only of the general knowledge of his craft.

Design in architecture is surely, as seen in the study of the highest design—the human figure—constructing beautifully. Certainly, the most intellectual part of the aesthetic satisfaction derived from the contemplation of the human figure comes from the perception of the harmonious grace of its constructional requirements.

Could we imagine a figure built up of compression members covered with tension-members and concealed beneath a coat of ornament ?

What we understand by architectural design has to be based upon the use of some material ; to what material shall we limit it ? Stone and wood only ? We do not know what the material of the future may be ; there may be no stone or wood. Times change, and we must change with them.

EXAMINATIONS AT THE ECOLE DES BEAUX-ARTS.

The spring entrance examinations of the Ecole des Beaux-Arts are unlike any others outside of Paris. For six months previously, says the London Architectural Record, the ateliers or studios are filled with men preparing for these examinations. Early on the chosen day the streets in the Quarter are filled with men carrying drawing boards and other utensils, and when at eight o'clock the gates of the Ecole are thrown open hundreds of young men file in, shouting at the top of their voices. As his name is called each goes past the guard and up the stairs to the little rooms, or loges, to secure a place in which to do his work. These loges are about 10 feet by 12 feet each, and hold six men comfortably. They are by no means ideal working-rooms, being dirty and ill-lighted, and opening off a long narrow passage; altogether they are about as uninspiring as one can imagine.

To the average person the idea of an examination suggests an ordinary room, presided over by a dignified professor with the utmost quiet prevailing, so that one can almost hear the scratch of the pencil. Who can picture an examination held while hundreds of men are singing, whistling or yelling and running up and down a passage ? Yet this is just what happens at the Beaux-Arts when the men are making the sketches of a given subject (required to be completed in twelve hours) which determine whether or not they shall enter the greatest architectural school in the world.

The uproar is constant, the noise deafening. From the moment the men assemble in the court till the last one leaves the school at night this noise is constant. First one set and then another takes it up. One wonders that any work can be done.

At the last examination there were no professors in sight, only guardians, whose principal occupation seemed to be to sell food and drink to the students and afterwards to dispose of the beer and wine that were left. As a result, at about four o'clock the guardians, who were supposed to see that the men did not make use of books or photographs, were assembled in one of the vacant rooms discussing politics and drinking and adding to the noise made by the students.

But notwithstanding all the apparent drawbacks the drawings were being made. After studying all the morning on the schemes, most of the men would eat and then start on the finished sketches. As time went on and darkness set in out came candles, for there is no gas or electric light in the rooms ; and about six o'clock some of the men handed in their finished work. Others, a little pressed for time, would be working with a will to finish before it was too late. When a party of visitors make their appearance at the door of this loge the busy one would call out "Charette !" And this would be respected, for it means, "I am in a hurry ; need all my time. Don't bother me." At eight the guardians collected the drawings, most of which were completed. Then the men went out, still shouting.

On Sunday the professors went over all the drawings and marked them. On Monday afternoon the results were announced. As early as 4 p.m. hundreds of men assembled in the court of the Ecole to wait until the doors were opened at seven. If noise prevailed before, it was nothing compared with that which now was heard. With nothing to do but wait, and with every nerve strained in expectation, it is perhaps excusable if the 500 young men let themselves loose.

Finally the doors of the great hall were thrown open and the men crowded in. The noise was stilled in an instant, and one could almost have heard a pin drop as the names of the men and the marks they received were called out. Thus the examination was conducted.

Salisbury Cathedral has the same number of windows as there are days in the year, is built in the early English style. They are triple windows, formed from an elegant combination of three lancets :

"As many days as in one year there be,
So many windows in this church we see ;
As many marble pillars here appear,
As there are hours throughout the fleeting year ;
As many gates as moons one year does view—
Strange tale to tell ! yet not more strange than true."

In the United States and also in Europe efforts are being put forth to secure the enactment of laws to provide for the examination and licensing of architects. The Council of the Society of Architects of London, in view of the Bill for the Registration of Architects now before the British Parliament, have held a series of meetings of architects in various towns throughout Scotland. Similar meetings have been held throughout England to ascertain the attitude of the architects on this important subject. The meetings were open to the public. With the growth and success of the movement for registration in other countries, should eventually come the amendments which are required to make the Ontario Architects' Act a workable and useful measure.

METHODS OF CONSTRUCTION IN RELATION TO COST OF INSURANCE.

The Underwriters' Association of Canada at a recent meeting decided to extend to the towns and smaller cities throughout the country the rule under which buildings are classified for insurance purposes according to the character and surroundings of the building. This system has been employed for some time in Toronto and is generally acknowledged to be the most equitable one. It is obviously unfair that the owner of a building belonging to a certain class who takes precautions to guard against its destruction by fire should be obliged to pay insurance at the same rate as another owner in the same class who takes no such precautions. The situation and surroundings of a building also have much to do with its desirability, or otherwise, as a fire risk. These circumstances ought to be taken into account by the insurance authorities when fixing the rate of insurance to be paid. The more strictly this system is applied the more general will become the construction of fire resisting and fire-proof buildings. It is said, on the authority of prominent insurance firms, that, during the last five years, the rate of insurance on this class of building in Toronto has been reduced by 50 per cent., which should certainly offer a strong inducement to persons proposing to build to employ fire-proofing methods and materials. Care should be taken, however, to see that when these materials are employed, the system of fire-proofing is carried far enough to place the building in the favored class. Prominent buildings have been erected in Toronto within the last three years in which the ceiling and floors have been fire-proofed while the stairways have been left open to act as flues and cause the destruction of the building in case of fire. A partial system of fire-proofing like this which disregards essential features, such as those mentioned, is valueless, and the money expended on expensive materials wasted. The record of fires in Toronto last year is very gratifying. The total number of fires was 686. For 328 no losses occurred, and for 221 the loss in each case was less than $100. The losses above insurance totalled only $13,289, and the losses without insurance to only $9,434. Only one fire extended beyond the building in which it started, which would seem to point to a high standard of efficiency of the fire department. To what extent improved methods of building construction contributed to this excellent showing is not known, but it may reasonably be presumed that some credit is due in this direction. The record of fire losses in the United States for the first six months of the present year shows the total losses to have been $88,935,000, as compared with $103,299,000 for the corresponding period of last year.

CANADA FOUNDRY COMPANY, LIMITED,

(SUCCESSORS TO ST. LAWRENCE FOUNDRY COMPANY OF TORONTO)

Engineers, Founders and Machinists

STRUCTURAL IRON AND STEEL WORK

Beams, Channels, Angles, Tees and Cast Iron Columns always in stock.

WRITE OR 'PHONE FOR ESTIMATES AND PRICES

Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited.
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the followowing terms: Architect's Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

THE DANGER OF PUTTING STRUCTURES TO NEW USES.

The partial failure of the Brooklyn bridge recently is another evidence of the danger which attends the imposing upon structures of duties which they were not originally designed to fulfill. The designer of this bridge had no thought that electric and cable cars would be run over it, and made no provision for such a contingency. Consequently, as the result of the extra strain imposed by the street car traffic, some of the rods have snapped, causing a sinking of the roadway, and necessitating the closing of the bridge to traffic. Many accidents from the same cause have happened, causing the collapse of bridges and buildings. It is quite a usual practice to put buildings to uses differing entirely from those for which they were designed, and to impose loads upon the floors many times in excess of those which they were intended to carry. The wonder is that in so many instances they manage to stand the strain. In view of this practice of overloading, architects should be careful in designing buildings for business uses to employ a factor of safety sufficient to cover all ordinary contingencies of this kind which are likely to arise.

The Ontario Portland Cement Co., Limited, has been formed at Brantford, with a capital of $450,000. The management is in the hands of President, E. L. Gould; Vice-President, W. S. Wisner; Secretary, E. Taylor; Directors, H. Cockshutt, A. Bixel, W. G. Elliott and the president and vice-president. The company propose to utilize marl deposits at Blue Lake, near St. George.

If you are looking for a high grade Finish for Floors

Granitine Floor Finish

Is unsurpassed in Durability and Beauty of Finish for Natural Wood and Parquette Floors, Linoleums, Oil Cloth, Cork Matting, &c.

Its transparency reveals the grain of the wood, and its preserving qualities increase the life of the floor.

Its sanitary properties are highly commended, as it closes thoroughly the pores of the wood against disease germs, and permits the floor to be kept thoroughly clean.

It is easier applied, more durable, makes better finish than wax preparations, and is free from all unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks; nor does soap, mud or water destroy its fine appearance.

WHO SHOULD LAY THE DRAINS.

For many years the custom prevailed among Toronto architects of placing in the mason's specification the construction of house drains. Since the enactment of plumbing by-laws, which compel the plumber to furnish to the owner a certificate that the drainage system has been inspected by the Health Department and found to be tight, some architects have thought it advisable to place all drainage work in the plumber's specification, so that they would have but one contractor to deal with. Other architects continue to follow the old plan, believing that it is to their advantage and that of their clients to do so. It is argued that the mason who has the putting in of the foundation of the building is more likely to carry out the drainage work in a more satisfactory manner than is the plumber who comes along after the foundation work is completed and is obliged to break away part of the foundation in order to make his connections. In a majority of the large cities on this continent, it is now the practice of architects to include the drainage work in the plumber's specications, for the reasons mentioned.

There is believed to be a good opening for brick manufacturers at Dawson City, where brick is now replacing wood for building purposes. Valuable clay deposits suitable for brick making have recently been discovered in the locality.

PROPOSED PUBLIC LIBRARY FOR MONTREAL.

Considerable comment has been aroused by the action of the Mayor of Montreal in making a request to Mr. Andrew Carnegie for money with which to erect a Public Library in that city. In reponse to the request, Mr. Carnegie has offered to give $150,000 for the erection of a building on condition that the city shall provide a site and expend $15,000 per year for maintenance. The consensus of opinion in Ontario at least appears to be that it is not becoming to the dignity of a wealthy community like Montreal to ask outside assistance towards carrying out a public undertaking of this kind. If Montreal feels its need of a Public Library its citizens are abundantly able to supply the necessary unds for its erection, and by doing so they would better mainain the self-respect and dignity of the chief commercial city of Canada.

ANCIENT MEASURES.

The measures of length used in the Bible, with their equivalents in our modern use, are given by an English contemporary as follows: The great cubit was 21·888 in., or 1·824 ft., and the lesser cubit 18in. A span (the long), half a cubic, or 10·944 in., 0·912 ft. A span (the less), one-third of a cubit, or 7·296 in., or 0·608ft. A hand's breath, 1·6 of a cubit, or 3·684in., or 0·304 ft. A finger's breadth, 1·24 of a cubit, or 0·912 in., or 0·076 ft. A fathom, four cubits, or 7.296 ft. Ezekiel's reed, six cubits, or 10·944ft. The mile 4,000 cubits, or 7,296 ft. The stadium, one-tenth of their mile, or 400 cubits, or 729·6 ft. The parasang, three of their miles, or 12,000 cubits, or four English miles and 580 ft. A day's journey was 33·164 miles, some say twenty-four miles. A Sabbath day's journey, 3,500 ft., or, as some authorities contend, 3,648 ft.

FIRE-PROOF GLASS WINDOWS
THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

A Commendable Idea.

The women's patriotic organization known as the Daughters of the Empire is to be commended for its wisdom in deciding to erect a permanent memorial of the approaching visit of the Duke of York. It was at first proposed to erect a temporary floral arch, but wiser councils prevailed, and the intention now is to construct a permanent gateway at the Bloor street entrance to Queen's Park. This gateway will consist of stone pillars in combination with wrought iron work of suitable design. This method of procedure is preferable to that of the manufacturers who are expending a considerable sum on a temporary structure which will disappear immediately after the royal visit.

Effect of Prices of Materials on Building.

ENQUIRY among architects goes to show that while the present building season has been an active one and on the whole satisfactory, many projects have been abandoned temporarily at least on account of the high price of lumber and some other materials which enter largely into construction work. Persons who contemplate building frequently forget that the present is a period of high prices for all other materials as well as those employed in building. It is scarcely possible to purchase an article of any description to-day as cheaply as five years ago. Why then expect to get buildings put up as cheaply now as then? The advance in prices is due to a strengthened demand, or in other words to increased prosperity. Vastly more money is being made by all classes this year than five years ago, hence the purchasing power is increased. Most persons contemplating the erection of buildings can well afford to pay say 20 per cent. more for their structures than would have sufficed for their erection in the times of depression. In many localities land values have gone up to an extent sufficient to offset the extra cost of building. So far as lumber, the staple building material, is concerned, the supply is rapidly decreasing every year, and higher prices must therefore be expected to rule for the future. No doubt when landowners shall have become thoroughly seized of the above mentioned facts, they will see the unwisdom of pursuing a policy of delay in the carrying out of their projects.

The Toronto Industrial Exhibition.

Notwithstanding the counter attraction offered by the Pan-American Exhibition, the number of exhibits at the Toronto Industrial Exhibition was as numerous as in former years. In live stock the exhibits were considerably greater, and the stable accommodation proved inadequate. The conclusion seems justified that the success achieved this year under adverse circumstances, might be greatly amplified if the Main Building and several of the other important ones, were replaced by modern structures designed to fulfil in a more perfect manner the requirements of exhibitors. That there is need for reform in the management is shown by the fact that after the opening of the Exhibition this year the roof of the Main Building leaked like a sieve. In consequence many of the exhibits were seriously damaged. The management should have known that the roof was defective, and the necessary repairs should have been made before the Exhibition opened. It would be unwise, however, to spend any considerable sum for repairs as the building is no longer capable of fulfilling the requirements. The support that has been given the Exhibition in spite of its many defects, is a guaran-

tee that if properly managed it will develop into an enterprise of vastly greater importance in the future. There were to be seen this year a number of exhibits from the United States in addition to those of Canada, a proof that the value of the Exhibition as a means of advertising is becoming more widely recognized. The presence of these foreign exhibits side by side with those of our own country, affords opportunity to make comparison between the quality of home and foreign productions. As a rule the result is a higher appreciation of the home article.

An Important Decision.

On the 22nd of July the House of Lords gave an important decision in the case of the Amalgamated Society of Railway Servants vs. The Taff Vale Railway Company, namely, that a Trade Union registered under the Trade Unions Act can be sued in its registered name, and the funds of the Union made available for payment of costs and damages where injuries have been inflicted by its authority. The action was based upon illegal acts, namely, watching and besetting, committed by authority and direction of the executive officers of the Union in connection with the strike of employees on the Taff Vale Railway. This judgment of the House of Lords is in reversal of the judgment of the Court of Appeal which held that the language of the statutes was not sufficient to warrant trade unions being sued for damages. The first decision was rendered by Mr. Justice Farwell, whose judgment has now been confirmed by the highest tribunal, and who in giving judgment said: "The contention of the defendant society implies that the Legislature has authorized the creation of numerous bodies of men capable of owning great wealth and of acting by agents with absolutely no responsibility for the wrongs they may do to other people by the use of that wealth and the employment of those agents." Lord Macnaghten in his judgment said: "I have no doubt whatever that a trade union, whether registered or unregistered, may be sued in a representative action if the persons selected as defendants be persons who from their position may be taken fairly to represent the body." It therefore appears that a registered Union may be sued in its registered name, and an unregistered Union through its proper officers. That the accumulated funds of the Unions can now be legally reached by persons and corporations who may have suffered damage by interference with their employees, will have a wholesome effect in keeping the agitators from continuing the methods of interference and persecution which have so frequently been practised in the past because they were exempt from legal process.

THE DEVELOPMENT OF MUSKOKA—AND A PRECAUTION.

The erection of the Royal Muskoka Hotel has brought luxury to Muskoka at last, and has probably broken ground for a new order of things. Hitherto Muskoka has been the poor man's paradise; there he could live in a hotel with board partitions between the rooms; sleep on a clanging spring bed, which substitutes sagging for softness; and eat food in which he could feel the modified enjoyment which comes from the conviction that it will be cheap. The new hotel is of a different kind. It is a well planned structure; spacious and, in a simple way, elegant; and aims at that degree of comfort which is indicated by the presence of the colored waiter. It is said that other hotels of the same sort are intended to be erected. We may therefore look for a change in the character of Muskoka. As surely as bad coin drives out the good so surely does the introduction of luxury strike at the existence of simplicity. We may look for improved buildings as a first symptom; a demand for wooden buildings with some design about them. This is an interesting class of work which returns better results for the amount expended than any other sort of building, if it is carried out with due appreciation of the merits of the material. We may however, look for the usual outbreak in the direction of imitation. Whether it takes the direction of castles and baronial halls, or a romance of humility and imitation log cabins, there are examples to start from, and even text books for the rapid worker. We can only look on helpless, and to some extent hopeless awaiting these developments in design. But there ought to be no doubt about the question of sanitation. The Muskoka Club ought to embrace, as a matter of necessity, all dwellers in the Muskoka Lakes; and should establish a rule, based upon the best science it can command, fixing a standard method of drainage from which there may be no departure. The foundation of life in Muskoka is the purity of the water; and this is assailed by the introduction of the sort of luxury that boasts, as this new hotel does, of its water service and drainage. It is popular to speak of Muskoka as a sort of Venice in the future; but there is this essential difference between the islands of Venice and the islands of Muskoka that in the former case there is an eighteen inch tide which twice a day sweeps all the city refuse out to sea, and though the process is not always complete and there are complaints about the smells of Venice, makes the place on the whole clean and sanitary. With the land-locked lakes of Muskoka, though they are deep, the case would be otherwise. Nearly every island is occupied now, and many points. Hotels are on the increase, and the exactions of competition soon require all hotels to be on a "modern" basis as regards drainage. Many cottages will without doubt follow suit, and the case will then be dangerous. The new hotel claims consideration on account of its "septic tank," through which all wastes must pass before they are delivered to the water—and perhaps this is sufficient. But it is impossible to feel the same delight in the purity of water into which the wastes of a populous hotel have been poured, no matter how scientific the sound of the process to which they have been exposed. Moreover, if the process is one which requires attention—knowing the unresting energy of nature and the laziness of man, we doubt.

It is not so much a question of the present case, where we may assume good management, as of the inferior class of hotel, upon which a system of drainage will be forced by the necessity of competition. Above all, when it comes to be a question of the insufficient labour (and often the volunteer labour) of a summer cottage, there is no certainty about the operation of anything that requires care. The only safety is in a rule absolute, that no drainage of any kind shall enter the water. The land is the place for drainage. The thousands of Israel lived in safety in their encampments, under the simple rule that every man should ease himself at a place without the camp, and take a paddle with him, to dig there and cover that which had come from him. The method of subsoil irrigation, to which this may be compared, should be adopted where there is a sufficient surface of turf near by, as there is at the new hotel, and as there is likely to be near any good hotel site; but Muskoka consists for the most part of an irregular rocky surface and the only method possible in ordinary cases will be simply to deliver the drainage over the surface. This method also has been put to proof by a nation. China, densely inhabited in parts, supports a people, with the strongest constitutions in the world, under a system of disposal of wastes upon the surface of the fields that is said to make it impossible for an Englishman to take a walk across the country, because of the filth which sticks to his trousers. The Chinese method is not commendable otherwise than as evidence that the surface of the earth is a safe place for the disposal of sewage products; or rather we should call them wastes, for they are not degraded to the quality of sewerage until they have been in a sewer. It is extremely probable that under any other system the land of China would not support its population and the yellow terror would have been upon us long ago. The land of Muskoka will not support its population now; but that even these rocks are capable of improvement is evidenced by the fact that earthworms (once undiscoverable in Muskoka) are to be found, fine and large, near the privies of the old Muskoka cottages. These old receptables are not models for the future by any means and, for a hotel are certainly impossible. The stuff must be conveyed by water to a suitable place and spread over the land; just as the saw-millers, when they were forbidden to throw their saw-dust into the water, pumped it up to the conduits, which carried it inland to convenient places. There is in the interior of most islands an unvisited area. If not it would be necessary to make such an area and prepare it for use. If there is a fall from the site of the house to this spot, the problem is easy; if not there must be an arrangement for pumping at intervals. For this purpose the windmill—which, with a tank, will be an indispensable adjunct for water service—could be utilized. There is no reason to suppose difficulty about contrivances, if the system is made compulsory; and, though this may be difficult, it ought not to be impossible, because it is necessary.

These remarks are suggested as applicable to Muskoka chiefly on account of the progress in that particular region which the establishment of the hotel indicates; but the situation tends to become the same in any of our small lakes which have become devoted to the uses of the summer cottager; and in all of these places consideration for the future, in the matter of drainage, becomes necessary as the population grows thick.

Acetylene Gas.

Here is a convenience which is making its way for use in both summer cottages and permanent country houses. It costs less than fifty dollars to install both piping and apparatus for an ordinary house, and the running cost is said to be about the same as that of coal oil. At this rate it has the advantage that experiment does not involve a paralyzing expense, and we may feel at liberty to suggest its application to country work, without having any knowledge from experience of the quality of the light. It seems to be a pleasant and steady light and has the advantage that, as the flame is very small, it does not easily flicker in the air. The light is therefore well adapted for out of doors use, for verandahs and to light paths and boat landings. There are many contrivances for the generation of the gas. The contact of water and calcium carbide is all that is necessary, and the aim of the best contrivances seems to be to generate gas only as it is needed. The release of pressure by turning a tap brings in some cases water to the carbide, in others carbide to the water, just in proportion as it is needed; that is to say in proportion to the release of pressure, or to the taps turned on. This facility of application in quantities as needed seems to tend not only to economy but to safety. There is a residuum of slaked lime which requires to be drawn off two or three times a week; an accumulation of a few buckets which may perhaps be made useful.

INSURANCE RATES IN RELATION TO RISK.

The Maritime Board of Trade is an organization which represents the local boards of trade in the principal towns of New Brunswick and Nova Scotia, and is an exceedingly enterprising body. The board meets once a year and discusses a variety of questions affecting the commercial interests of the maritime provinces. At the seventh annual convention held in Chatham, N. B., on August 21st and 22nd last, a number of important subjects were considered. Among these was the question of fire insurance rates. This was taken up in view of the reported intention of the insurance companies to increase the rates. The testimony of the representatives who spoke on the question went to show that the insurance rate was not governed as largely as it should be by the character of the risk. One speaker remarked that twenty years ago before the advent of electric lights and fire extinguishing appliances, when stores were lighted by oil lamps and stove-pipes were everywhere, the insurance rates were 100 per cent lower than they are to-day. It was stated that in Charlottetown the promise was made that the rates would be reduced as soon as a good water works system was installed, but that this promise had not been fulfilled, on the contrary the rate had been increased. It was said that with the exception of a few large conflagrations, the fire loss in the maritime provinces had been considerably less than in other parts of the Dominion, and the opinion was expressed that the people of these provinces were being called upon to pay for losses elsewhere. A resolution was adopted protesting against any increase in the rates, and declaring that in the event of an increase being imposed, a united effort be made to induce American and other companies to accept the business. It was also resolved that the insurance companies be requested to separate the maritime provinces in their insurance calculations from the rest of the Canadian business.

MEASURING ROUND TIMBER.

The usual practice, in measuring round tapering timber, is to take the girth of each piece at the middle of its length. A quarter of the girth is then squared in inches, and multiplied by the number of feet run in the log, the resulting figures being divided by 14, which gives the answer in cubic feet. A tape measure, known as girthing tape, is often used by timber measurers. It is 12 ft. long, marked with ordinary inches along one side, and also with feet reduced with scale—1 in. = 1 ft.—showing the cubical contents of 1 ft. on the back of the tape behind each figure.

BY THE WAY.

The firm hold that electric lighting has obtained on public favor is exemplified by the fact that in a number of the new dwellings now being built in Rosedale and other choice residential districts of Toronto, no gas piping for lighting purposes is being put in. A single gas pipe entering from the rear suffices to give the supply required for cooking purposes.

× × ×.

THE main building at the Toronto Exhibition which must shortly be replaced by a more modern structure, has had quite an interesting history. It was originally built in 1852 on King Street West on a site which is now included in the asylum farm. On the occasion of the visit of the Prince of Wales in 1860, a grand ball was given in his honor in this building. In 1878 it was taken down and rebuilt on its present site, another storey being added.

× × ×

A good story is told by an English trade journal of a master builder, who, having heard that the men did not start work at the proper time, thought he would drop down about half-past six one morning and see. Going up the yard he caught sight of a joiner standing smoking, with his kit not even opened. Simply asking his name, which he found to be Malcolm Campbell, he called him into the office, and handing him four days' pay, ordered him to leave at once. After seeing the man clear of the yard, he went up to the foreman and explained that he had made an example of Malcolm Campbell by paying him off for not starting at the proper hour. "Great Scot, sir!" ejaculated the foreman, "that chap was only lookin' for a job."

× × ×

IN 72 days the elevator in the tower of the new municipal buildings in Toronto, carried 39,833 persons to the top of the tower to see the great clock and obtain a bird's eye view of the city. As the elevator will accommodate but twelve persons, more than three thousand trips were required, and at times the corridors were lined with a crowd of people waiting their turn to make the ascent. No doubt there were thousands of visitors to the building who did not visit the tower. It will thus be seen what a point of attraction the new city buildings have already become to strangers visiting the city, of whom the number steadily increases each year. It is desirable that the building on the erection of which so much money has been expended, should be made increasingly interesting as time goes on by the addition of mural decorations, paintings and sculpture.

INDUCEMENTS TO FIRE PROOF CONSTRUCTION.

A correspondent sends the following extract from the New York Insurance Exchange Schedule, relating to fire-proof buildings:—

"EXCEPTIONAL CONSTRUCTION.—For fire-proof floor surfaces of cement, concrete or asphalt, deduct 5 per cent. If floors inclined for carrying off water with scuppers, deduct 2 per cent. Fire-proof woodwork, trim, etc., deduct 5 per cent."

"If the same reduction was made in Canada as the above," says this correspondent, "it would induce people building to take advantage of the insurance reduction and use fire-proof materials."

THE PROTECTION OF BUILDINGS FROM LIGHTNING.

A paper on this subject recently read by Mr. Alfred Hands, before the London Architectural Association, concludes as follows:—

As to the methods for rendering our system of protection perfect. We must first of all decide on which are the parts of the building liable to be struck by lightning, and protect them either by separate conductors or by branch conductors carried to one or more mains to earth as may be necessary, and we must see that these conductors afford as little resistance as possible. The joints must be soldered so that they will not only be perfect at the time they are put up, but will remain perfect. The earth connections must also be made so that this path is at least as good a one as other paths about the building; and besides this we must carefully study our building, both inside and out. We must take into consideration all the metals used in its construction, both as regards their relation to the conductor system and to one another, and take such precautions that neither division of the discharge shall occur unless we intend it to occur, nor sparking in places where sparking would do harm. It is here that the skill and experience of the expert have to be displayed, and I cannot give you any rules for your guidance on this matter, for buildings differ so much in their construction and arrangement that rules appliable to one case would be absolutely useless for another. Nothing is of use but knowledge and experience, and, as I have already indicated, these cannot be imparted or acquired in a short space of time. I can only say that in some cases connections are made and in others the dangerous metals are avoided, but that great discrimination is required as to what metals are connected and what avoided. Sometimes dividing the discharge between several paths or over a wide extent is the best plan, and sometimes other plans are adopted according to the exigencies of the case or the particular combination of dangers which one may find to exist.

I may, in conclusion, discuss a matter which is of great importance to architects, and that is as to what parts of a building are liable to be struck, and which, therefore, require protection. I have devoted many years to this question, and have examined many thousands of buildings which have been struck, first, with the object of formulating a theory, and afterwards to prove that theory; and I propose putting this before you as briefly as possible. The main principles are simple, and possibly it is the very simplicity of the matter which has led to its being overlooked. The popular idea is that it is the highest point of a building which is struck, but probably some of you may have met with cases in which others very much lower down have been damaged. I have come across hundreds such. The explanation is that the nearest part of the building to what I may call the point in the cloud from which the discharge originates gets struck, and the highest is not necessarily the nearest. A discharge occurs between two planes or points, one of which is in the clouds and the other is in the ground; the building is merely an object en route, as one might say, which forms a path of less resistance than the surrounding air. Now, a lightning-conductor does not attract lightning except as, being of metal, induction and consequent difference of potential takes place more strongly in it than in the surronnding non-conducting materials, and in this respect the thin line which is intended to protect the building from lightning is insignificant compared to the other metals used in its construction.

Brickwork, although non-conducting to a certain extent, offers a lower resistance than air. Therefore it would be contrary to science for a discharge to pass over a chimney-stack or gable-end to strike a lightning conductor merely because it is metal, when probably the gable-end or chimney has a much larger extent of metal just below it. Even if the lightning-conductor affords the best path to earth, the path of least resistance would be through the gable-end or chimney and the house to the conductor, rather than through a corresponding distance of air, to get to the top of the conductor. We have to consider two kinds of discharge, one the most dangerous type, which occurs fairly straight through the air in an almost vertical line, and the less dangerous flashes which occur in a somewhat oblique line, and are generally meandering in their course. These latter flashes are often called forked lightning, though this is a misnomer, and are popularly, but mistakenly, supposed to be the most dangerous. It is the straighter flashes which do the most harm; those which are capable of breaking almost straight through the air without having to go out of their course to take advantage of any little conducting matter, such as moisture, which will assist them on the way. The meandering flashes are not by any means to be ignored; it is only in comparison with the straighter ones that they are mild.

In arranging what parts of a building require protection, we have to consider the various points in the sky from which the discharge may originate, and so arrange our system that the conductor, or one of its branches, will form the nearest part, no matter from what direction the discharge may come. There is, of course, a limit, to the angle of obliquity, and this limit should be about 40 degs., and my observations have led me to infer that the greater the angle of obliquity the milder the discharge. We hear reports sometimes of buildings having been struck by lightning in absolutely unaccountable places, such as lightning missing a tall spire and striking the nave close underneath it, or even striking through a window. Like all other so-called vagaries, freaks, or perversity of lightniug, such peculiarities do not exist except in the minds of people who do not understand the matter. Lightning is a force of nature, and, like all other natural forces, is governed and regulated by laws more unchangeable than those of the Medes and Persians; therefore, if we find cases which do not quite agree with our preconceived ideas, we must admit that we either do not know the law, or that we have overlooked some important factor of the case, and not put it down to a sudden and capricious change in the laws of nature.

In arranging as to which parts to protect, we can consider this question as to which would be the nearest part, and we can take it that these are parts which might be struck; other parts higher than these may be absolutely safe if they come well within a line drawn from one to the other, provided other circumstances are equal; but they may not be, for metals either inside or outside the building, and other circumstances, may complicate the question so far that this rule does not entirely apply. Notwithstanding all the difficulties that I have pointed out, absolute protection is possible if the building is thoroughly studied. We can either protect it so that we can say not a brick or stone shall be disturbed, or we may say we will protect it so that the inmates shall be safe and the building shall not be set on fire or damaged to any extent—we may say that a stone finial at this end may be knocked down, or a few bricks or tiles disturbed there, and that we will risk that, as we do not consider this damage worth providing against; but if we do this we must realize that we are running the risk, and if the stone finial is thrown down, or the bricks or tiles displaced, we must consider that we deliberately took the risk, and that it is not a failure of our system of protection.

In conclusion, I can only advise you not to make the general error of providing your conductors of exceptionally large size under the mistaken idea that by providing your conducting path of exceptional capacity, as it is wrongly called, you can ignore the scientific aspect of the question, for no increase in size of the conductor will compensate for this.

ST. PAUL'S CATHEDRAL IN DANGER.

As the result of rumors which have lately been in circulation regarding the stability of St. Paul's Cathedral, Mr. Somers Clarke, the architect to the Dean and Chapter, has addressed a communication to the Times, giving the results of his observations and examinations of the building. He states that owing to the expense involved, the foundations of the cathedral were not carried down to the bed of hard clay, 40 feet below the ground surface, but were spread out as much as possible and made to rest on a layer of "pot earth" over a bed of sand and shingle above the clay. The numerous tunnels which have since been made for sewers and underground railways, have caused uneven settlement of the foundations, dislocation of the arches of nave, choir and transept, and subsidence of the west front with its heavy towers and bells. The outer wall of southern transept, which is between 8 and 10 feet thick, and has an outer face of Portland stone with a lining of Oxfordshire stone, is out of perpendicular, and in consequence of the strain it has opened from east to west. The north side of the cathedral is, however, perfectly solid. Upwards of one hundred years ago the building was strengthened by the insertion of iron ties and the dome encircled by great iron chains. It is now proposed to insert iron ties in the transept walls. Another method proposed by Mr. Charles Reilly, is to carry the piers down to the sub-stratum of blue clay. The cost of underpinning is estimated at £220,000. This architect recently strengthened the Stock Exchange by underpinning to a depth of 50 feet the isolated stone piers which support the building, each of which weighs 300 tons. This was accomplished without cracking the plastering in the interior of the building.

NOTE.

As a result of the recent decision of the English House of Lords, holding the funds of labor unions liable for damage caused by the official action of the unions, the Taffvale Railroad Company has begun suit against the Amalgamated Society of Railway Servants for one hundred thousand dollars damages, incurred by the unlawful action of the Society during the strike of last year. The Blackburn branch of the Weavers', Winders' and Warpers' Association has also been served with papers in connection with a strike in a factory. The Trades-Union Congress has appointed a committee to endeavor to find some legal means of protecting the funds of unions from attack.

BUILDING MATERIALS AND CLAY PRODUCTS.

The report of the Ontario Bureau of Mines for 1901, gives the aggregate value of the building materials produced during the year 1900, including under this term stone, lime, common brick, pressed brick and terra cotta, as $2,689,351, compared with $2,621,282 in 1899, an increase of $67,069. An error crept into the statistics of building stone and rubble for 1899 by which the value of the product was given as $1,041,350 instead of $667,532. The comparative table for the last two years is as follows :

	1899.	1900.
Building stone, rubble, etc.	$ 667,532	$ 650,342
Lime	535,000	544,000
Common brick	1,313,750	1,379,590
Pressed brick and terra cotta	105,000	114,419
Totals	$2,621,282	$2,688,351

Judging from these figures says the report the building trade remained in a fairly active condition. Part of the increase is due to a rise in prices, the average cost of lime per bushel in 1900 being 13.9 cents as againt 12.3 cents 1899, and common brick being valued at 5.73 per thousand as against $5.61 in 1899. The output of other clay products for the two years compares as follows : drain tile, paving brick and sewer pipe showing a falling off which is more than made up by an increase in pottery.

	1899.	1900.
Drain tile	$ 240,246	$ 209,738
Paving brick	42,550	26,950
Sewer pipe	138,256	130,635
Pottery	101,000	157,449
Total	$ 522,152	$ 524,772

The manufacture of cement continues to expand, the total production of 1900 being much larger than in any previous year. The increase is wholly in Portland cement, the natural rock variety being smaller in output and value than in 1899. The raw materials for an excellent quality of Portland cement—marl and clay—being so abundant in Ontario and the demand for pavement and constuction purposes being so great and constant, there is every likelihood that the production will continue to increase. The number of cement works reporting to the Bureau last year was nine, of which four made natural or rock cement and five Portland cement. In addition to the factories now in operation, one or two others will place their product on the market during 1901. The detailed statistics for 1900 are as follows :

Kind of Cement.	Number of works.	Number of workmen.	Wages for labor.	Product bbls.	Value of product.
			$		$
Natural rock	4	90	32,760	125,428	99,994
Portland	5	485	166,143	306,726	598,021
Totals	9	575	198,903	432,154	698,015

There was an increase in the total quantity of cement produced in 1900 as compared with 1899 of 70,117 barrels and in value of product of $136,749. The average price at which the cement was reported to the Bureau was 79 cents per barrel for natural rock and $1.95 for Portland, as against 84 cents and $2.00 per barrel respectively in 1899. That the home market is not by any means wholly supplied by the product of Ontario works is proven by the fact that during the fiscal year ending June 30, 1900, the imports of cement into Canada amounted to 1,312,170 cwt. as follows:

	Value.
From Great Britain	$ 249,280
" United States	55,569
" Belgium	156,213
" Germany	59,331
" other countries	200
Total	$ 520,593

The duty paid on the importations was $151,075.06.

It is worthy of note that a marked change took place during the year in the proportion of cement imported from the several countries of origin. In the 12 months ending 30 June, 1899, the imports were :

	Value.
From Great Britain	$ 125,778
" United States	52,878
" Belgium	232,434
" Germany	73,135
" other countries	146
Total	$ 484,371

It will be seen that the imports of Belgian and German cement which had risen from $79,370 and $15,603 respectively in 1896 received a decided check, while those from Great Britain were almost doubled, and constituted even a larger proportion than in 1896 when they were $123,436 worth out of a total importation of $252,882. The preferential tariff, whatever may be its operation with respect to other articles, certainly seems to be effective with cement.

While the above statistics show that the importations of German and Belgian cements into Canada have largely decreased, and in like proportion those from Great Britain have increased. British statistics show that the product of continental factories, principally Belgian, is going into the British market at the rate of 270,000 tons per year, which is equal to ten per cent. of the production of the British factories. So that the gain that Great Britain is making in the Canadian market is being offset by the loss of home trade. The statement is made that the Belgian cement which is finding its way into the British market is not being sold at a loss, but owing to the excellent equipment and labor saving methods employed in factories where it is produced, it is bringing to the manufacturers a fair margin of profit. British manufacturers are in consequence being urged to modernize their works, thereby reducing the cost of production, and placing themselves in position to compete with the foreign material. Within the last five years the manufacture of Portland cement in the United States has been greatly extended and perfected, and the product of the mills across the border is this year being placed on the Canadian market in large quantities. Several new Canadian factories are ready to begin operations and others are projected, so that in the near future the capacity of the home mills will more nearly approach the requirements of this market. There is need for caution on the part of those who are thinking of engaging in the business, to see that the manufacturing capacity does not run in advance of demand. This has already happened in the United States, hence the eyes of manufacturers there are being turned to Canada and other foreign markets.

With a view of securing better sanitary regulations in municipalities where waterwork and sewerage systems exist, a resolution was passed by Dominion Trades and Labor Congress that the Executive of the Congress urge the Legislative Assemblies of the Provioces to amend the health act so as to compel such municipalities to appoint a competent plumbing inspector.

ARCHITECTURE AND ENGINEERING AT McGILL.

The accompanying illustrations will convey some idea of the character of the equipment at McGill University for the teaching of Architecture and Engineering. It will be seen that provision is made for the instruction of the students from both the artistic and practical sides. McGill owes to Mr. W. C. McDonald its magnificent building and equipment for engineering and architectural instruction, and is understood to be now on the look-out for a generous benefactor to bring the endowment for teaching purposes up to a standard in keeping with the building and equipment.

In the Department of Architecture, of which Professor S. H. Capper is the head, and Mr. H. F. Armstrong, lecturer, the equipment consists of a representative collection of casts of architectural detail and ornament and sculpture ; of photographs and illustrations; an arc-light electric lantern ; a large collection of slides, diagrams and models ; and a library for architectural study. The Architectural, Freehand Drawing and Modelling Classes are open to women students.

A Room in the Architectural Department.—McGill University.

The course in this department begins with the second year, the first year being preparatory. The work of the second year is of a general character, and is planned to combine to some extent the work of the Architectural and of the Civil Engineering students.

The third and fourth years are devoted to more specialized architectural study in various branches, and a fifth or graduate year has been organized for advanced study in design. For those students who desire to devote themselves more especially to the engineering side of architecture, the course is modified to include additional mathematics in the third year, and the advanced course of Theory of Structures in the fourth year. Such students devote proportionately less time to architectural drawing and designing.

In the second year the historical course embraces a rapid survey of Architectural History from ancient Egyptian to modern times. The great eras of European civilization are successively dealt with, and the evolution of styles is traced in their constructional and ornamental forms and methods.

In the third and fourth years the lectures are arranged in continuation and extension of this general course. Renaissance and Modern Architecture are studied in the third year ; while a course covering both third and fourth years comprises more detailed study of Ecclesiastical, Domestic and Public Architecture, and deals with the historic evolution of architectural styles and with the problems and requirements of modern work.

Instruction in drawing is given during all four years, Freehand Drawing (ornament and figure) from the cast and Architectural Drawing occupying much of the students' time during three years course. Modelling in clay is included in the third and fourth years.

Problems in Architectural Design form the basis of work in the Architectural Drawing class from the earliest available period, being at first more especially combined with the study of the Classical Orders.

A course of lectures is included upon General Art History, so as to place the architectural student in touch, not only with the decorative details of the different architectural styles, but also with contemporary forms in other branches of art, especially the decorative arts employed in building.

For the scientific side of professional study the courses in Mathematics are very fully developed in the first and second years, being continued in the third year also by those who elect to take the advanced course in Theory of Structures. Descriptive Geometry is studied, as well as elementary Shades and Shadows and Perspective. A course in Surveying, both practical and theoretical, is also included ; and a short course in Geology is given in the fourth year.

Theory of Structures and Strength of Materials form one of the chief subjects of study in the third year, the course also comprising instruction in Graphic Statics as well as supplementary work of a practical nature in the Testing Laboratories.

A full course on Building Construction and Architectural Engineering has been organized for the third and fourth years, common to both architectural and engineering students. It includes also sanitation and Hygiene, Heating and Ventilation; Specifications and Professional Practice.

During the Session 1900-1901 a special course of lectures was arranged to be available for those who are engaged in office work during the day; it embraced the subject of Architectural Styles, their Features, Mouldings and Ornament. This course was planned with a view to preparation for the examinations for Associateship now held in colonial centres by the Royal Institute of British Architects; it comprised a detailed study of the three great divisions of historical architecture, Classical, Mediaeval and Renaissance, in accordance with the examination-programme of the Royal Institute.

The course will be repeated in session 1901-1902, if sufficient students come forward.

Carpenter Shop.—McGill University.

In the Drawing Rooms.McGill University.

LICENSING OF ARCHITECTS IN CALIFORNIA.

The new California law requiring architects to secure certificates in order to practice in that state is about to go into effect. All architects not having sent in their applications for certificates to practice architecture and approved previous to September 23, will be barred from receiving a certificate and will be required to pass an examination.

The subjects upon which the applicants for a certificate of competency to practice architecture, shall be examined are as follows:

Demonstration of ability to make practical application of knowledge in the ordinary professional work of an architect, as follows: 1, merit as investment; 2, planning; 3, construction; 4, design; 5, rendering.

Materials and construction of buildings, eleven subjects as follows: Foundations, concrete work, stone masonry, mortar, brick masonry, structural iron and steel work, carpentry, joinery, sheet metal work, plastering, painting.

Strength of materials, eight subjects, as follows: Tension, compression, shearing, transverse strain, structural columns, floor beams, girders, trusses.

Sanitation, three subjects, as follows: Plumbing, heating, ventilation.

Electrical construction as applied to buildings.

Supervision of all the foregoing subjects as applied to buildings.

Each subject of each sub-division shall be graded by the committee on examination, and the applicant whose grading shall be 75 per cent. or over, shall be entitled to a certificate of competency.

A penalty of not less than $50 nor more than $500 will be inflicted on persons practising architecture without having obtained a certificate.

All plans issued from the office of a certificated architect must be impressed with a seal having his name and place of business and the word, "certificated architect."

A CENTRAL SQUARE FOR TORONTO.

The Board of Control of the Toronto city council has declined to lease the land opposite the city hall for the purpose of a public square on the terms offered by the owners. The portion of land offered, 130x107 feet, is too small. If the whole of the land from Bay to James street cannot be secured on satisfactory terms, the project might as well be abandoned. A less area would not answer the end in view, which is to provide a public square within the business district and improve the surroundings of the new city buildings. The city has the right to expropriate the land, but this would probably involve costly arbitration proceedings. It is to be hoped that a way may yet be found to accomplish this much needed improvement.

THE ART EXHIBIT AT THE PAN-AMERICAN EXPOSITION.

"Canadian artists will have to wake up" said a well-known Toronto artist the other day on his return from an inspection of the art exhibit at the Pan-American Exhibition. "They are too much given to thinking that they know it all and that there is nothing good outside a particular school. The Canadian art exhibit at Buffalo is perhaps up to the standard of the average work shown there, but is certainly far below the best work exhibited. The art exhibit as a whole is representative of all schools and contains work of equal merit in the broad style of treatment as well as in a style almost as refined as that required for miniature portraits. There are to be seen a number of pictures which are of the highest excellence. It is noteworthy that in the United States painting in oils is taking the lead, the demand for water colors having greatly diminished of late. The artist in oils works with greater certainty of securing the effect desired than is possible with water colors. Referring again to the Canadian exhibit, the space allotted for this exhibit was only 150 square feet but this was doubled later on after the exhibit had been arranged for, consequently the Committee were compelled to get together from different sources and on short notice sufficient pictures to fill the additional space. On this account the selection could not be as carefully made as was desirable."

Canadian Pavilion at Pan-American Exhibition.

A receipt for waterproofing blue prints runs as follows:—Immerse in melted paraffin until saturated a number of pieces of an absorbent cloth. When these are withdrawn and cooled they are ready for use at any time. To apply to a blue print, spread one of the saturated cloths on a smooth surface, place the dry print on it with a second waxed cloth on the top, and iron with a moderately warm iron. The paper aborbs paraffin until saturated, and becomes translucent and highly waterproof. The lines of the print are intensified by the process, and there is no shrinking or distortion.

CHEAP HARDWARE.

Suitable and appropriate trimming is something that is too olten slighted both by owner and architect, and the tendency to cheapen the entire contract by reducing the cost of the hardware is daily evidenced by the appearance of some of our buildings, says a writer in the Architects' and Builders' Journal. As a rule the hardware is a neglected matter until the building is nearly completed, and then as an offset to the expenditure in other details, the allowance for this is cut down.

The result is what one would look for in such a case. A handsome house or apartment with everything of an elegant appearance, the floors tiled, the walls beautifully frescoed and the woodwork handsomely polished, while the hardware throughout is of the cheapest class, not fit for a tenement. There is an abundance of such hardware on the market. Take in the first place the front door which is at all times before the eyes of the public. If trimmed artistically, it at once makes a good impression, and to be artistic does not necessarily mean at the same time expensive, for a good lock that is reliable can be had at a very reasonable figure, and a plain grille will pay for itself in effect. Ornamental hinge straps will also add wonderfully to the appearance of a house, while on the other hand a cheap lock and trimmings will cheapen a door no matter how handsome it may be. A door cheaply trimmed makes the same impression as a soiled shirt front on a person, both are criterions by which you may judge of the rest of the make-up.

Locks for interior doors need not be either elaborate or intricate, but should be in keeping with the other appointments. If an ornamental design is too costly, then plain trimmings is in good taste, and, like black clothes, always in keeping. When the cheap ornament designs have the word "cheap" woven in the pattern, the owner makes a sad mistake in using them. The public notices and is influenced by such apparently little things. Plain bronze hardware is but very little more expensive than the cheap trade ornamental goods and its application shows better taste.

Then again the utter disregard of the general architecture of the building in applying trimmings is a very common mistake. The effect of an elegantly carved door of Romanesque style trimmed with colonial hardware is not only an example of bad taste, but is a mistake that means a money loss, as a tenant may not be artistically educated, still a feeling of inconsistency will be experienced, for no person is so constructed that discord will not affect him to a greater or less degree.

No clause in the contract is so much neglected and none of more importance than the one relating to hardware. In the matter of butts there are many varieties from which selections might be made, but experience and judgment should be brought to bear in this matter. Bronze iron butts for the purpose of hanging the door do the work as well as the more expensive solid bronze, but they will not remain but a very short time. The appearance of the iron on a

hardwood door where the lock trim is bronze certainly is not pleasing. Then again the mistake of cheapening the trimming by using a light butt is a serious one.

Nothing can be more provoking than a door that drags in closing or that will not close at all. While a settling in the building affects this matter more or less, it is more often the case of the butt being too light or too small, so that the weight of the door causes a sag that the butt will not withstand. A loose joint butt is a little less expensive than the loose pin, but it is not so durable nor convenient, as in a loose joint there is one bearing, and consequently more tendency to give and wear, thereby causing the same trouble as in the case of using a light butt. A loose pin has three bearings, and in case of necessity to remove the door it is much easier to do so.

A conspicuous fault in the present cheap trimmings of apartment houses and residences is the fact that the keys are interchangeable, or, in other words, the key that opens the hall door is more than likely to operate the lock on the pantry door or the linen closet and vice versa. This may be overcome by specifying in the contract that the locks have two or more tumbles and all be different.

The tendency to use cheap hardware seems to prevail more with the owner than the architect. In a great many cases the owner is not a man competent to select good trimmings for his house, and therefore should turn it over to the architect, who will select something in keeping with the house for which he has drawn plans.

TORONTO ARCHITECTURAL EIGHTEEN CLUB.

The Annual Meeting of the Toronto Architectural Eighteen Club was held on the 23rd inst., when the following officers were elected for the ensuing year: Mr. Eden Smith, president; Mr. C. H. Acton Bond, 1st vice-president; Mr. J. C. B. Horwood, 2nd vice-president; Mr. C. D. Lennox, 3rd vice-president; Mr. J. P. Hynes, secretary-treasurer. A discussion took place on the subject of architectural education and the improvement of the Toronto Industrial Exhibition. A special meeting of the Club has been called for the 30th inst. to further consider these matters.

TEST OF A FIREPROOF FLOOR.

A test was recently made in the presence of the architects of the building, the assistant city engineer, and others, of an expanded metal floor, constructed by the Expanded Metal and Fireproofing Company, Limited, in the new St. Lawrence market building, Toronto. A weight of over 20,000 lbs. was placed on an area 12 feet x 4 feet, or to figure it out as a distributed load, about 420 lbs. per square foot of area. This load, which was up to the limit of the strength of the girders, was carried without sign of failure, and was considered entirely satisfactory. This building has nearly 50,000 feet of unbroken fire proof floor area.

ONTARIO ASSOCIATION OF ARCHITECTS.

The attendance at the weekly luncheons, which have been maintained without interruption during the summer, is now steadily improving. These luncheons are a popular feature, affording opportunity for frequeut social intercouse as well as the discussion of matters of interest to the profession.

Request has been made by the Toronto Architectural Sketch Club to be granted the use of the Association rooms in which to hold their Saturday evening meetings. It is understood that the Association is willing to comply.

ARCHITECTS AT CRICKET.

An interesting cricket match was played recently at the Woodbine by teams representing the Ontario Association of Architects' and the Toronto Architectural Eighteen Club. The Association won by 70 runs, the following being the scores:—

The bowling of Pearson, Siddall, Baker and Langton for the Association, and the wicket keeping of Rolph and fielding of Howard for the Eighteen Club were conspicuous features of the game.

NOTES.

In a large office building recently erected in Cleveland, known as the Rose building, compressed air is supplied to the offices, being intended as an attraction to physicians and dentists. A 6 x 8 x 8 inch Marsh compressor operated to maintain a pressure of 40 pounds to the square inch and a pressure tank 3 feet in diameter and 8 feet high are located in the basement and a 2 inch main is carried around the basement supplying a number 1¼ inch risers. Branches are taken trom these under the wood floors and a ¼ inch pipe carried to an outlet in each room at the chair rail. A similar system of piping, only of larger sizes, has also been installed for supplying illuminating gas for mechanical purposes, the illumination of the building being electric, and the heating, steam. The gas outlets are at the floor to distinguish them from the air outlets, which are at the chair rail as stated.

Under the same pressure a clean brass or lead pipe will generate a much greater velocity of flow in any fluid than a clean iron one, all other conditions being the same. The difference is ascribed by Sullivan in his "New Hydraulics" to the difference in specific gravity of the metals composing the pipes. It does not follow, however, that this comparison holds between all substances. It does hold between the metals and in general between the various grades of one specific substance. Thus the metals may be compared and the advantage with the denser ones. But there are substances much lighter than metals which give a greater flow with the same head. Thus, an asphaltum coated pipe will carry considerably more water with the same head than an ordinary plain pipe. There are various grades of asphaltum and the purer qualities are found to give the best results. So it is apparent that comparing different grades of the same substance, or related substances, the advantage in friction coefficient will be in favor of the denser one.

LEGAL.

Building owners should be warned that if there are law-suits about their property there is great risk in making charges against the architect or builder. Although the amount claimed was only 70l. 2s. 11d., the case Cheale v. DePinto, which was tried at the Hastings County Court, is as much of a warning as if it were heard in the High Court. The plaintiff, a timber merchant, took over the contract for the completion of the building of a house at Bexhill. He executed the work, and the architect had certified it was properly carried out. Counsel for the defendant interposed at the beginning of the case by saying he was instructed that the words "to the satisfaction of the architect" were not in the original deed. That was an allegation of a most serious kind. But evidence was not brought forward to support it. Mr. Alton, the architect, said the orders for extras were often given in his presence by the defendant, and several witnesses testified that the defendant did give such orders. The defendant said that he told the original builders that he had decided to expend no more than 250l., and no extras were to be recognized unless there was his written authority. Two architects were called to prove that the work was inferior and the measurements did not correspond with the specification. An effort was also made to upset the claim on the ground that the original contractors had filed their petition March 10, and therefore the assignment of the balance of the contract a month afterwards was invalid. Judge Martineau decided in favour of the plaintiff, saying that practically the whole of the work to be done had been performed. There were a few deviations, but he thought every shilling claimed was due except two guineas in respect of these deviations.

The apparent ease with which actions for damages against architects arising from carelessness succeed is ominous. Two cases have been heard within the last fortnight. At Stafford, in the case of Boyes & Son v. Adshead, which was allowed to go by default, the damages were assessed by a jury. The plaintiffs complained that the work was not attended to, and said they must engage another architect. That course had to be followed, and the second architect received 32l. 10s. 6d. in fees. It was alleged that some part of the work was not properly executed. The Under-Sheriff said the claim was reasonable, and the jury accordingly assessed the damages at 52l. 16s. 6d. An adjourned case, Harris v. Babb, was heard at Wrexham. The plaintiff, an architect, sought to recover 30l. 16s. for fees. The defendant put forth a counterclaim of 150l. as damages on account of plaintiff's incompetence and negligence. The jury found for the plaintiff for the amount claimed, but they assessed the damages at 82l. 14s., and the judge said the defendant was not liable for a claim for bricks amounting to 47l. 5s. 9d., or in all 129l. 19s. 9d. From that sum was deducted 30l. 16s., plaintiff's fees, and judgment was accordingly entered in favour of the defendant for the net sum of 99l. 3s. 9d. In both instances the work done was not large, and the amount of damages is therefore more remarkable. It is too generally supposed that an architect is a privileged person, in fact an independent judge, and so long as he is supposed to act with "reasonable skill," he is secure from liability for damages. It is now evident that judges have become more exacting, and unless it is manifest that other architects of experience and skill would act in the same way, a claim for damages has a chance of succeeding. The remedy, of course, lies with architects. —London Builders' Reporter.

PUBLICATIONS.

A general treatise on school architecture, by Edmund M. Wheelwright, architect, of Boston, has been published by Messrs. Rogers & Manson, of that city. Examples are presented of the most typical and practically suggestive schools of Germany, Austria, Switzerland, the Scandinavian countries. All details of school construction are considered, yet the information is studiously condensed within the limits of a convenient handbook, which is made readily accessible by an unusually full index.

A new book on mill construction prepared by Mr. H. G. Tyrell, C.E., has been issued by the Engineering News Publishing Co., of New York. It treats of the general design of this class of buildings, contains descriptions and illustrations of details of construction and gives figures and diagrams showing the loads which may safely be imposed.

TORONTO INDUSTRIAL EXHIBITION NOTES.

The Canada Foundry Company, Toronto, had a complete display of structural iron and steel work, fire escapes, iron stairs, etc.

Rice, Lewis & Son Company, Limited, Toronto, in a special building had an extensive display of brass mounted beds, mantels, tilings for floors and walls, bronze builders' hardware, etc.

The warerooms of the Gurney Foundry Company on King street west, contained as usual an interesting display of all kinds of heating appliances, and received many out of town callers.

The Pedlar Metal Roofing Company, Oshawa, had a very attractive display in their own separate building of metal ceilings, fireproof windows and wire-bound glass, spun metal, relief work in copper and zinc.

The Dominion Radiator Company, whose works are in proximity to the Exhibition grounds gave a cordial welcome to many visitors who dropped in to inspect the numerous styles of radiators in their well appointed show rooms.

The Gurney Tilden Company, Limited, Hamilton, had in their own building a large display of stoves, furnaces and builders' hardware. The building was very prettily decorated with bunting. Mr. A. J. Brenton, Toronto representative, was in charge of the exhibit.

The Imperial Varnish & Color Company, Toronto, had an original display of high grade architectural varnishes for interior and exterior finishing, also their famous "Grantitine" floor finish and "Elastilite" varnish for interior and exterior use. All varnishes are put up in cans with the company's name and address stamped on a brass seal.

In The Canada Radiator Company's advertisement in this issue appears a photo of their exhibit, which shows a few of the artistic designs of radiators manufactured by them. While they endeavor to give a radiator of handsome appearance, their chief feature is the system of circulation of water through the radiator. By causing the water to pass alternately up first and down second section of entire radiator, they secure a distinct difference in temperature of water in return and supply pipes and in consequence a positive and rapid circulation is maintained.

The Metallic Roofing Co. had one of the most attractive and original exhibits in the Main Building, the special feature which attracted crowds of people being a dome temple finished in white marble and built of sheet metal. In this temple was a twenty-five ton coining press in operation which stamped the Company's name and address, and formed a very neat twentieth century souvenir in six colors. In addition this company were showing metallic shingles, embossed plates for interior decorations, steel lathing and general architectural sheet metal work.

One of the largest exhibits at the Exhibition was that of Clare Bros' & Company, Preston. It consisted of a complete line of stoves, ranges and heating systems, including a number of new lines recently added. The most prominent feature was their "Hecla" furnace, to burn coal or wood. They have found it necessary to manufacture the "Hecla" in a series of five sizes to meet the several requirements, the largest sizes suitable for schools, churches and public buildings. The "Preston" boiler attracted considerable attention from parties interested in hot water heating. The construction of this boiler is entirely different from any other make. It provides vertical circulation, with its water-ways thoroughly surrounded by fire, and being a one-piece boiler is entirely free from joints and is practically a self-cleaner.

Mr. Baines, the eastern representative of the Preston Metal Shingle & Siding Company, was a visitor at the exhibition.

The J. F. Pease Company, Limited, Toronto, had a large and varied dis play of hot water boilers, wood and coal furnaces, combination heaters, etc. The company also exhibited a new apparatus for which they control the Canadian patent, the "Ideal" Heater and Ventilator for schools and churches. It is claimed by the Company that this heater will furnish a thorough system of heating and ventilation for buildings which have no basement. The new "Economy" hot water boilers have several original and effective features of construction. The company claim that this boiler has the largest area of heating surface exposed to the direct rays of the fire of any round boiler on the market. The joints are made with screwed nipples and no bolts, gaskets, or packing of any kind are required. Another feature is the ease with which the boiler can be set up; it being claimed that it can be erected in less than half the usual time.

STUDENTS' DEPARTMENT.

ANCIENT ENGLISH CATHEDRALS.

Winchester, in its earliest form, must hold the place of the most ancient. The original cathedral claims, on very apocryphal authority, to have been built in 177, by the newly-converted British King Lucius, on the site of a great Pagan temple. Another was built in 313, and another in 871. The present pile, regarded in its various parts, is of at least seven principal dates; and if viewed in its minor features, its smaller accessories, its remodellings, and its restoratians, must be pronounced to belong to ten centuries. The oldest parts of the edifice belong to a pile in the Saxony style, by the famous architects and bishops of Winchester, to Ethewold in 980. Lichfield Cathedral is said by some authors to have been erected in 300, and by others in 667, and rebuilt in 700. Canterbury is very ancient; it is said to have been founded by St. Augustine, as also is Rochester. They appear to be of about the same date. The former was founded in 598, and partially rebuilt in 1080; the latter between 600 and 1000. Exeter had a cathedral standing in 1050.

THE COLONNADE.

Colonnades are of various forms and dimensions, and assume different names according to their application and uses says the Builders' Reporter. When in front of a building or in the interior of a quadrangle they are called porticoes; when surrounding a building of any shape, peristles; when double or more, as in some of the ancient temples, and the circular peristle in front of St. Peter's at Rome, they are polystyle. No people have made more use of colonnades, or with greater effect, than the ancient Egyptians, many of their temples being literally thickset, both in the interior and exterior, with colonnades of every description. The Greeks were more simple in their arrangement, and their colonnades were mostly distributed into porticoes and peristyles, both monostyle and polystyle. Their most magnificent example is perhaps the Temple of Jupiter Olympius at Athens. Baalbec and Palmyra present also various examples of splendid colonnades. Of modern works, the magnificent colonnade of the Piazzo di San Pietro at Rome, the work of Bernini, is at once the grandest and most beautiful. It consists of 280 columns, and 48 pilasters of 40 feet high, raised on three lofty steps. It is surmounted by a balustrade, on which are 88 colossal statues 15 feet in stature. Colonnades are among the most beautiful and splendid works of architecture, and in the hands of a man of taste and science are capable of the grandest and most imposing effects.

Mr. J. Wilson Gray, architect, of Toronto, is at present on a visit to Great Britain.

Canadian Office and School Furniture Co., *Preston, Ont.*

Office, School, Church and Lodge Furniture.

Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.

THE TORONTO ENGINEERS' CLUB.

The first meeting of the above club following the summer vacation, was held in the club rooms, King street west, on the evening of the 3rd inst. In the absence of the president, the chair was occupied by Major Gray.

Several new members were elected and other business transacted.

A letter was read from the secretary of the Canadian Society of Civil Engineers, stating that the proposed summer meeting at Buffalo had been abandoned owing to the few favorable replies received to the circular sent out to members.

Owing to the unavoidable absence of the author, the paper announced to be given by Mr. Cecil B. Smith, on "Parks, Squares, and Drives for the City of Toronto," and the anticipated discussion thereon, was not forthcoming, but will probably form the chief feature of the programme of the next meeting to be held on the 1st of October.

Part III of Engineering Studies by Charles Evan Fowler, M. Am. Soc. C. E., published by the Engineering News Publishing Co. of New York, is devoted to descriptions and illustrations of some of the most celebrated stone arched bridges of England.

If you are looking for a high grade Finish for Floors

Granitine Floor Finish

Is unsurpassed in Durability and Beauty of Finish for Natural Wood and Parquette Floors, Linoleums, Oil Cloth, Cork Matting, &c.

Its transparency reveals the grain of the wood, and its preserving qualities increase the life of the floor.

Its sanitary properties are highly commended, as it closes thoroughly the pores of the wood against disease germs, and permits the floor to be kept thoroughly clean.

It is easier applied, more durable, makes better finish than wax preparations, and is free from all unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks; nor does soap, mud or water destroy its fine appearance.

Manufactured only by

The Imperial Varnish & Color Co., Limited

TORONTO, ONTARIO, CANADA.

The King of Siam is said to have in one of his country seats a pavilion of a very extraordinary kind. The tables, chairs, and cabinets with which it is furnished are of crystal; the walls, roof, and sides are formed of glass, 1 in. thick and a fathom in breadth, and so finely united with mastic as transparent as glass itself that not a drop of water can penetrate the building. A Chinese engineer constructed the pavilion in this manner as a certain remedy against the insupportable heat of that country. It is 28 feet in length by 16 feet in breadth, and is placed in the midst of a large basin, paved and covered with marble of different colors. The basin can be filled with water in a quarter of an hour and emptied as rapidly. When those who are to occupy the pavilion have entered the gate is shut, the seams stopped with mastic to prevent the entry of water, and, the sluices being opened, the large surrounding basin is filled to the top, so that the whole pavilion is placed under water, with the exception of the top of the dome, which allows for the passage of air for the respiration of those within. Nothing can be more delightful than the agreeable coolness enjoyed in this delicious pavilion, while all around is scorched and burnt up by the intolerable heat of the sun.

Imitation marbles have been made from the fine dust of certain woods and the dust of ivory and similar waste. A mixture of sawdust and phosphate of lime with a binder has been used as a material for taking casts of sculptures, and has been called "Similibois." Slabs for parquet floors have also been made from sawdust, as well as plates for bas-reliefs, art castings, panels and decorations. Terra-cotta lumber and artificial lumber are both instances of the utilization of sawdust. Sawdust compositions have also been used for sidewalks and dinner plates."

FIRE-PROOF GLASS WINDOWS
THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

The Royal Visit.

Canada tendered a right Royal welcome to the Duke and Duchess of Cornwall and York, who have just left our shores after a month spent in visiting all parts of the Dominion. It is to the credit of our future King and Queen that they should have undertaken a nine months journey, traversing two-thirds of the earth's surface, with the object of acquainting themselves with the people and conditions existing in the various parts of the great British empire. The information which they have acquired will enable them to more capably discharge the functions of their high station. The people with whom they have come in contact feel that the bond of sympathy and loyalty which binds them to the Empire has been further strengthened. Great commercial advantage is also likely to accrue to Canada from the descriptions of the country and its resources and opportunities written by representatives of the leading British and American papers who accompanied the Royal party.

Building Conditions.

THAT a large volume of building is in progress throughout Canada is evidenced by the scarcity of tenders for work of ordinary character as well as labor skilled and unskilled. It is not unusual of late for an architect to solicit tenders from a dozen contractors and receive but one or two. Skilled workmen in all trades are in demand, and there are also too few laborers. The requirements in some trades are said to have been met by bringing in workmen from Buffalo, where, according to the observation of Canadian visitors, there is not to be seen a single residence in course of construction. While a high degree of prosperity prevails in Canada, there is no perceptible tendency towards a building boom. The activity is the result of a legitimate demand for more and better buildings.

Development of the Canadian North-west.

The encouraging statement has lately been published that of the 23,000,000 acres of land granted as railway subsidy by the Dominion Parliament to the Canadian Pacific Railway Company, 9,000,000 acres have already been sold. Most of these lands extend along the line of the railway, but there is also a large tract in Northern Alberta. The rate at which the land is being taken up in the Northwest is the best assurance that in a few years a large population will flow into that territory and develop its agricultural and other resources. With the population will come a steadily increasing demand for the skill of the architect and builder, and for construction materials of all kinds adapted to the climate and the requirements of the people. The illustration pages of this number show the development in this direction which has already taken place at Winnipeg, where some of the leading banks and other financial institutions have erected buildings which in point of cost and dignity of appearance are fit to grace the streets of any city in the world.

The Canadian Exhibit at Buffalo.

The impression given the visitor to the Canadian Building at the Pan-American Exhibition is that Canada is a purely agricultural country where buffalos, bears and all manner of wild animals abound. The building contains only specimens of grain, wild animals and furniture. While it is important that the advan-

ages which we can offer to the farmer, the sportsman and the tourist should be adequately displayed, our capabilities in art and industry should also have prominence, otherwise strangers will receive a wrong conception of our rank among the more highly civilized countries. It is true that the art gallery contains a small exhibit of pictures by Canadian artists, that in the Mining Building are to be seen some excellent samples of Canadian ores, and that in other departments such as live stock and farm and dairy products, Canada is well represented. But these exhibits are divided among various buildings and therefore do not impress the visitor as would a collective exhibit in one building. At least half the available space in the Canadian Building might profitably have been used for small, attractively arranged exhibits which would have served to give the visitor a bird's-eye-view of Canada's resources and development in a dozen or twenty different lines, and a measurably accurate idea of her advantages as a place of residence. People of refinement are loth to remove to a raw country, and it is to be feared that the character of many of the exhibits which we have made at foreign exhibitions has been such as to convey the idea that Canada is that kind of a country. Perhaps the best method of removing any such false impressions would be to inaugurate in Toronto on a suitable scale a Dominion Exhibition, and invite foreigners to come and see for themselves the beauty and capabilities of our country and the skill of our people.

HALF-TIMBERED DWELLING HOUSE FROM PRUSSIAN SAXONY.

The Toronto Building By-Laws.

REFERENCE has been made on several occasions to the necessity for a thorough revision and compilation of the enactments of the Toronto City Council for many years past with respect to the erection of buildings. The legislation on this subject has been of a fragmentary character, extending over at least a quarter of a century. When enacted the various by-laws were printed separately on sheets or in pamphlet form. No attempt was made at compilation in one volume. Many of the by-laws are now entirely out of print, and architects, builders and others are consequently unable to learn what are the provisions of the laws which are supposed to govern the construction of buildings. Such has been the confusion which has existed for many years past, that even the officials whose duty it was to see that the laws were observed, were unable to interpret them. The condition of affairs is well illustrated by the fact that there is declared to be no restriction to prevent the erection of factories, livery stables and such like constructions on the most choice residential streets. We have in mind an instance in which the rear wall of a six or seven story block has been built close alongside a well designed and cosy home on an attractive west end street. The owner of this home is thus without warning deprived of beautiful surroundings and much of the actual value of his property. Something might be accomplished if the present shameful condition of things were pressed upon the attention of the council by a joint deputation from the Ontario Association of Architects, the Guild of Civic Art, the Builders' Exchange and real estate interests. It will be remembered that some years ago a new building by-law was drafted and submitted to the council by the O.A.A., and that was the last that was ever heard of it. Although it involved the arduous labor for many months of a committee of the leading architects of the city, it apparently never got beyond the pigeon-hole in some city official's desk. If the council have not the time or disposition to grapple with this important matter themselves, it is due to the many interests affected, that following the example of the city council of Montreal, they should avail themselves of the work which has already been done by public spirited citizens.

NOTES FROM THE PAN-AMERICAN EXPOSITION.

As comparison with the World's Fair seems to be inevitable for any one who writes about the Pan-American, this comparison may be made—that the Buffalo Exhibition, from the comparatively small space it occupies is, as a study, more within the range of practical politics. Its area of 350 acres is not far beyond the area necessary and feasible for permanent exhibition grounds, and a study of the sources of its beauty is likely to have practical application in the question, which is a live one, how to improve such grounds.

The popular cry all summer has been about the "colour scheme" and the illuminations. Both are in consequence somewhat disappointing.

After so much talk we expect to find the "Rainbow City" a striking exhibition of colour; but it is not. The colour is harmonious and pleasing, but not bright. One does not think of the buildings as coloured. They are not white, that is all. And being neither white nor coloured—essentially coloured that is to say—they are in that respect out of touch with the spectacular idea; they class, in appearance, with the permanent monuments of architecture and are so far, in spite of their beauty, imperfect. The buildings of the World's Fair were criticized by the French as crudely academic. The more freely designed French Fair buildings may be as good or better, (it is hard to judge from such illustrations as we see,) but it certainly seems, in recollection, as if the very academic character of the Chicago buildings, and their improbable whiteness, was the source of their success. They were an abstraction; something outside of ordinary experience; the sort of buildings that are usually left to painters or poets, "who," as Bacon says, "build at small cost."

The designers of the Buffalo Exhibition adopted colour as part of their plan, with the avowed intention of making a variation from the effect of the Chicago buildings. But to compete with the Chicago buildings;

to approach no nearer to the prosaic, it was necessary to transcend ordinary building material in colour as much as the World's Fair did in purity. It cannot be said that this has been done; the problem of a coloured fair is open for further development, but it will take a mighty man to tackle it.

Apart from the misleading of the popular cry, there is no cause for disappointment in the buildings. After all it is not the buildings that make the Fair so much as the grounds, and these are a triumph of spacious appearance, combined with a real compactness which, to one who toiled over the long distances of the World's Fair, is an unexpected joy. It is the plan of the grounds that is the principal source of beauty and will best repay study, for this gives the key to the successful planning of a pleasure Fair. Buildings are the main motive and give character to the whole, but their architectural function is to form a background for the spaces. A good sky-line and mass, and a play of light and shade, are the principal necessities. It is impossible to take any real detailed interest in the reduplicated enrichments which form the detail of such buildings; they are of use only in the broad way, to mark points in the design and to give it scale. A Fair is an open-air show and the real enjoyment of it is in sitting down and viewing some portion of the scene. A building thus gets real attention only as a whole, as a background for a space.

The grounds should constitute the beauty of a Fair quite as much as the buildings; each is equally dependent on the other, and the Pan-American forms an admirable study of the successful treatment of grounds, to give them interest and beauty and to assist the perception of space. One may deduce from it principles for guidance such as the following: Trees and shrubs are valuable not only for their individual beauty but for the softness of their texture and their rounded forms; a balustrade shows perspective like nothing else, and without insisting too much on hard lines; water is invaluable as a level surface with which everything else is unconsciously compared; all isolated objects near at hand give tone and scale to the distance, and upon these all possible beauty of detail should be lavished, for the eye occupies itself with them particularly. Statues are, of course, capable of the greatest beauty, and their white colour is a gain in the neighborhood of foliage, but dark objects help the sense of space better, and the Pan-American has examples in its band-stands, kiosks, fixed seats, flag poles and lighting posts, of useful objects which are made ornamental and assist the general effect. The advantage of fountains seems to be to a great extent their varying motion; the restlessness of the water produces peace in the beholder. A scene or building is more likely to receive attention and appreciation if there is a fountain in the foreground. Motion is also, no doubt, one source of the pleasure we receive from flags, and a constant irruption of kites in the sky over one corner of the grounds of the Pan-American—which certainly did add to the gaiety of the scene—may have been official and had a scientific intention in the same direction. One is reminded of Mr. Olmsted's prescription of waterfowl for the lagoons at the World's Fair, to induce movement and sparkle in the reflections. At the Pan-American this is carried too far. The fountains in the main court rise from the principal basin and fall back into it, troubling the water so much that there are no reflections. Is anything quite so useful as a reflection? It makes composition automatically. Who has not seen a familiar bit of common-place roadside turned into a picture, when the melting snow forms a pond large enough to reflect a tree or a bit of sunset? The canal at the Pan-American was too narrow to be of much use in this way, and it did not appear to be an attraction except when the illuminations were on, which brings us back to illuminations, and the consideration of why they disappointed expectation.

In the first place the much-talked of gradual illumination was evidently only a device to save the electrical arrangements from strain. The public seem to have agreed that it was a wonderful spectacle to see the lamps glow a little at first and increase gradually to full power. The present writer experienced nothing but impatience, until the light came out to its proper strength. The genius of electric lighting is for sudden illumination, and if it could have been arranged to flash the whole thing out at once there would have been something to talk about; as it was, it is necessary to record a disappointment.

When the light was out in full force it was certainly fine, especially the tower, where the lights were thickest, giving the effect of massed diamonds. But one did not look long upon it, nor did those people do so whom one heard saying it was worth coming such numbers of miles to see. Why was this?

The truth is that the illuminations were—if one may use the word for anything so splendid—a little dull. They did not illuminate, in the primary and Pickwickian sense of lighting up. The buildings were completely extinguished and in their place appeared rows of lights marking out the main lines of the structure, like a pattern in pin holes held up before a light. It was a transformation scene all right, but when seen it was seen. There was nothing to watch, the lights did not even twinkle.

At the World's Fair, in which the illuminations were rudimentary by comparison, there was one feature which might give a clue to a more interesting mode of illumination. Surrounding the dome of the Administration Building were torches of natural gas, flaming many feet in height, which occupied the eye more than all the rest of the illuminations, not only from their own appearance, but from the play of light they cast upon the dome. Gas torches form part of the iron fence of some clubs in Pall Mall, and the light which the street and buildings receive from them, when the gas is turned on for a great occasion, is peculiarly exciting. It is a question af movement again. The frozen music of the Buffalo illuminations is too frozen to retain attention long, except, by the way, in the canals. These are uninteresting by day, because they are too narrow for the reflection of the buildings along their sides to appear as reflections; a surface of dirty water is all that catches the eye. But at night, when, under the illuminations, the passage of boats ruffling the water makes its surface a surface streaked with dancing fire, the canal, which is deserted by day, becomes popular.

Something of the nature of the waving light from gas torches, cast upon the buildings and grounds, would make a more beautiful scene at night than do the present illuminations, and the interest would be sustained by a sort of liveliness in the light and shade.

But the use of such enormous quantities of gas as would be required seems indefeusible. To use gas is to use material, whereas the production of electricity, where waterpower is available, is a mere matter of the wear of a few engines. Electricity is the available means of lighting. But its possibilities are not confined to strings of lamps, and a hint may be taken from the lighting-up effect of gas.

There are details of the Buffalo illumination which show how lights placed on the retired surfaces, instead of on the projecting surfaces, show up, with delicate tones of light and half light, the places of the building. This by itself would have more in it than the pin-hole system of making out only the leading lines. It is the difference between a line elevation and a perspective in light and shade.

The search light on the tower was also suggestive. The business of the search light was to pick out the statues and fountains in the principal court and show them up against the dark sky. Its efforts were a relief to the monotony of the general illumination. It showed things up instead of concealing them, and showed them up in a striking way. Even the movements of the search light from point to point were worth following. When it was changing its point of application and feeling about for another statue, the green of the grass under its glare was of extraordinary brightness, and suggested how brilliant the scene would be if lighted up by an application of this kind of light.

What is wanted is a combination of methods. There are three that may be used: 1st, the application of diamonds (clear lamps) and pearls (clouded lamps) to the outer surface, as at Buffalo, to decorate such features as should receive particular distinction; 2nd, a general scheme of lighting up surfaces by lamps concealed or withdrawn from view, on reverse or retired planes; 3rd, the use of search lights, that is to say, of lights thrown from an external point, in order to produce pictorial effects, to key up some portions of the scene above the rest, with possibilities of moving or mingling lights and perhaps of a suspicion of colour.

Of these three methods, the designers of the Pan-American Exposition adopted, it may be safely said, that with the least possibilities. We can judge therefore, from the splendour of the Buffalo illuminations, what may yet be done.

W. A. LANGTON.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

At the first regular meeting of the season of the Canadian Society of Civil Engineers, a discussion took place on Mr. Cecil B. Smith's paper on "The Sewage Output of Toronto," read at the last spring meeting.

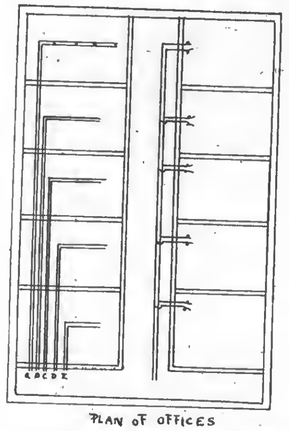
LECTURES ON ARCHITECTURE.

Prof. Capper has commenced the delivery of a series of lectures at McGill University upon "Architectural Styles, their Features, Mouldings and Ornament." The course is preparatory for the examinations qualifying for associateship in the Royal Institute of British Architects, the Royal Institute having announced its intention of holding such examinations at colonial centres. It is intended specially for architects in practice, and their assistants, who may be unable to attend lectures during the ordinary working hours of the university. It comprises a study in detail of the three great divisions of historical architecture, Classical, Mediaeval and Renaissance, in accordance with the programme of the Royal Institute, the lectures being illustrated by diagrams, lantern-slides, and casts. The lectures will be given in the architecture class-room, Engineering building, Monday, Tuesday and Thursday, from 5.30 to 6.30 p.m.

OFFICE BUILDING WIRING.

The difficulty is constantly arising in office buildings regarding meters for single offices or en suite. Architects find it difficult to foresee who will probably occupy offices in a building at the time it is wired, and it is impossible to know how to arrange the feeds for meters. If a separate feed is put in each room, some tenant comes along and may require a suite of three rooms or more, or possibly a whole flat, and then arises the difficulty of arranging so that one meter will do for all. At present wires have to be run through the walls from one room to another to accomplish this end, which necessitates a lot of unsightly wires and also damage to the building, and then it is not a job.

By referring to the cut it will solve the trouble. On the right hand side of the corridor the wires shown represent the usual method employed. It will show a feed wire running the length of corridor and a tap running into each office. On the left hand side is the



method I recommend, and which, although familiar to some, is not generally known. I have recommended it and installed it in several cases, and it gives great satisfaction.

At some convenient location on each floor, space is either found or provided to receive all the meters for all offices on the same floor, and the letters A, B, C, D and E represent the circuits radiating from this meter board, to each office. By this means any two or all offices, or in fact any combination required, is made in short order behind meter board without any defacing of walls or make-shift arrangements being resorted to. We have in some cases wired buildings and had all the meters in the building in one cupboard in basement. This is satisfactory for small building, but for large building each floor should be equipped as above.

H. F. STRICKLAND.

Toronto, October 10th, 1901.

NOTES.

The management of the Central Canada Fair at Ottawa have decided to purchase yearly a number of pictures from among those sent by artists to the Fair, thus in time to establish a permanent art gallery. This year five hundred dollars worth of pictures were bought. The result has been that a number of well-known artists have signified to the secretary their intention to send each year in future not less than four pictures to the collection at the Fair.

MANITOBA CORRESPONDENCE.

Most of us no doubt have frequently heard the expression, "The unexpected is sure to happen." When all things seem to be running smoothly a break occurs and the whole machinery is out of gear. This in some measure illustrates what has been taking place in this city during the past weeks.

It was news to most of us that there was any trouble between the carpenters and the contrcctors, and we were looking forward to a good season's work free from strikes or any of those labor clouds which sometimes darken the horizon and obscure the sky of building prosperity.

To measure up and make a fair estimate of the whole subject is not an easy matter. Whichever way the scale may turn there is always the other side to reckon with, so that it is necessary to handle a contention of this nature with great care and intentional impartiality.

We find that a large number of the carpenters have been on strike for the past two months. They contend that they are not paid enough for their labor, and we think in a measure their contention is grounded on a good foundation. That the better class of mechanics in this branch of the building trade should be paid a higher rate of wages is we think allowed by all fair judges of such things, but there seems to be a desire on the part of the men to obtain a high standard wage for very inferior labor.

A man should be paid what he is worth and the times will allow, but good men should not be placed on a plane with inferior men, and to ask for such men 40 cents per hour with the addition of 10 cents, 20 cents or even higher per hour for over time, is out of the question. There is a large amount of unskilled labor in the market, useful and necessary no doubt in its place, but it should be remembered that this labor should not expect to receive the same wage that high-class labor can command.

Some two years ago a carpenters' strike took place here which ended in an arbitration, and the terms were that the minimum wage was to be 27½ cents per hour. This arrangement the men say was not satisfactorily carried out by the contractors. This may or may not have been the case, but the jump from 27½ cents to 40 cents per hour as the minimum wage, is in our estimation too great. Nor do we think the men ever expect to get this, but are really working and striking for the purpose of getting the contractors to acknowledge and treat with their union, which the contractors on their part say they will not do. So the matter rests, and in the meantime men are out of employment, work is delayed, some of it being put off for another season, while a bitter feeling to some extent is growing up between employees and employers.

We think the men as a body made some mistakes from their own stand point. The time selected was not a right or proper time to fix matters of this kind. It should be done before work starts, which would be fair and right to all. Public sympathy would be more likely to follow them than at the present time. Again the effort does not seem to have been a united one on the part of the whole trade, and consequently cannot expect to be the success it otherwise might have been. Besides as has been stated the minimum wage is set too high, and to make this a lever to compel contractors to acknowledge a union which has no standard of excellency, but only a standard of membership, is bad in principle.

As to the contractors we think some action should be taken by them to try and arrange on a fair basis disagreements regarding wages. Men should be paid a proper renumeration for a fair day's work, good men should be encouraged by good payment, for the class of work done, so that by this means a higher standard may be obtained. If the arrangement of two years or so ago has not been carried out in a fair or honorable manner, then we say it should be, and no advantage should be taken of workmen who have their labor to sell.

A fair and honorable dealing between employer and employees will conduce to a better state of feeling and assist to bring about that happy time when strikes shall be a thing of the past.

Since the above was written the strike has been declared off by the men, but with the notification that the same demand will be made early in the coming year. We cannot estimate on what may or may not take place in the future, but we think the demands of the men must be somewhat altered before they are likely to be accepted by the contractors. We trust that for their own good the men will see this and that another strike will be averted.

The building trade has not been very brisk this fall for some reason or other; we presume the strike has much to do with it. Work let early in the season is being wound up, so that from what may be seen just now building operations will close early.

In our rambles we have noticed in a brick building now nearly completed that there has been adopted a certain class of iron construction. In fact almost the whole work above the basement has been carried on iron girders supported on cast-iron round or box columns. Does it not seem bad practice at this date to depend on cast-iron to support a heavy building? Is there not danger in case of fire? These supports may become heated to such an extent that a stream of cold water striking them would cause fracture, and thus endanger the safety of the structure. From the position of these supports it would seem out of the question to cover them with a proper fire proof covering. Cast-iron unprotected does not seem to be the safest way of supporting bricks and mortar.

During the past summer there have been some heavy rain storms in this city, when such an amount of water fell that some of the sewers were not large enough to carry off the flood, and in consequence the water backed up in the cellars, and in one instance we know of the pressure of the water was such as to lift the cement floor at the centre. On investigation to find the cause of this unusual occurrence it was found that the cover of the catch basin was closed and weighted down by goods, and that the water not having this outlet, spread through the weeping drains, penetrated under the floor and exerted sufficient pressure to lift the cement top and crack it. The question arises should a rain fall of such exceptional character be taken into calculation when figuring up the capacity of sewers to carry off flood water. To work on the basis of an average rain fall would not meet the case, so we presume the only way is to run chances as a thing of this kind may not occur for years. Still it is a factor in general sewer construction, we might do well to consider and in some way arrange for.

Winnipeg, October 5th, 1901.

FIRE PREVENTION.

There recently closed at Berlin an exhibition of materials and appliances designed to prevent destruction by fire. The exhibition was housed in temporary buildings erected for the purpose on a site in the suburbs of Berlin having an area of 80,000 square meters. Some of the exhibits were shown in the grounds surrounding the buildings. The exhibition was divided into six sections, as follows :

1, Fire Extinction ; 2, Assistance in case of Need and Danger ; 3, Street Cleansing, Street Paving and Cognate Works ; 4, Fire Prevention ; 5, the well-being of the personell of Fire Brigades ; 6, Art, Literature and Education.

From the Builder it is learned that " Section 4 was one of the most extensive sections in the Exhibition. A great deal of ingenuity was devoted to the production of novel forms of fire-resisting construction, some undoubtedly valuable from a scientific point of view, others valuable only from a commercial point of view, being merely excuses fot building up trade. The use of iron in fire-resisting construction is very generally adopted, and its adequate protection not always sufficiently carried out. There are numerous examples of so-called fire-proof floors, for example, in which the lower flange of rolled iron joists are left exposed, but there are on the other hand, many others in which the protection of the iron is rightly regarded as an imperative necessity.

" One material which is largely employed for the protection of iron, especially in columns and stanchions, but also in girders and joists, in cork-stone, a material made of cork dust and various kinds of cement and plaster. As a non-conductor of heat and a slow burning material, this uudoubtedly is not without value. Asbestos, in combination with lime, cement, and plaster, is also largely employed in various forms. Kiesel-Guhr or fossail meal, on account of its valuable non-conductive property, is also used in various forms for the protection of iron, in bricks, sheets, and slabs, formed by a combination of Kiesel-Guhr with some cementing compound. Several firms show iron protected by rope made of asbestos, cork, or Kiesel-Guhr and jute, the chief advantage being apparently the ready application of the material, which is then usually finished with a plastered surface.

" Besides these slow-conductive materials, brick and concrete in various forms and arrangements are also employed. Very considerable use is made by many patentees of porous brick, that is, brick which has been made of clay mixed with sawdust which is consumed in the process of burning the brick, thus rendering it lighter and almost as easily ruceptive of nails as coke-breeze concrete. Hollow bricks, either of ordinary brick earth or of the porous manufacture, are not uncommon. Dovetailed and keyed bricks or blocks are in bewildering variety, and very considerable spans are shown constructed in this way. Examples of floors of 6 ft. and even 8 ft. span and only 4 in. thick are frequent. In some cases light iron rods or bars, one might almost say laths, for their thickness scarcely exceeds that of hoop iron, are used in the joints of the brickwork to give increased tensile strength to the lower part of the floor's section. An interesting development of this brick construction is seen in self-supported or hanging partition walls, some of which are quite startling, as, for example, the exhibit of Pruss & Koch, of Berlin, who show a structure of two self-supporting parallel walls 13 ft. span and 18 ft. high, with a cross wall 21 ft. span and 18 ft. high between them, with a doorway cut out in the middle of t. One of the side walls is 2½ in. thick, the other of the two thicknesses each 2½ in. thick with a space between of 6 in. The cross wall is 1½ in. thick. These walls depend largely upon hoop-iron vertical ties ; but in another instance, shown by Lorene, of Berlin, we see walls 12 in. thick and close on 15 ft. span, with a height of 7 ft. 6 in., built of keyed brick alone, without iron. These walls, moreover, carry a brick roof 6 in. thick. Thus the whole structure in this case forms a hut 15 ft. square internally, carried only on four angle piers.

Combinations of iron and concrete are numerous, and in many the construction has but a small amount of iron which is embedded in the lower part of the concrete. As an example of this, we may instance the flooring shown by Paul Zollner & Co., of conerete 4½ in. thick, 14 ft. span, with ⅜ in. iron rods 4½ in. apart. Another example is that by M. Czarnikow & Co., a floor nearly 20 ft. span of concrete, 9 in. thick, with iron bars 1½ in. by 1-16 in., 2 in. apart. As a tour de force showing what can be done with glass, the Aktien Gesellschalt for Glasindustrie, of Dresden, have erected a considerable sized pavilion wholly of glass—walls, roof and floor. Glass bricks, hollow and solid, and wired glass of various thicknesses and patterns, are the chief components of this remarkable structure."

A SULPHUR AND SAND CEMENT.

Professor Brown, a St. Louis man, is said to have invented or re-discovered a combination of sand, cement, and sulphur, which he claims possesses qualities far superior to concrete, and which can be produced at less cost than that material.

Professor Brown claims for his new discovery that it is acid-proof, a non-conductor of electricity, waterproof, a non-conductor of heat and cold, and that it is indestructible, being impervious to all attacks of fire, temperature, climate variations, time and decay. The compound can be mixed and moulded upon the spot where it is to be used, and when dried it becomes as hard as granite, and will take a high polish.

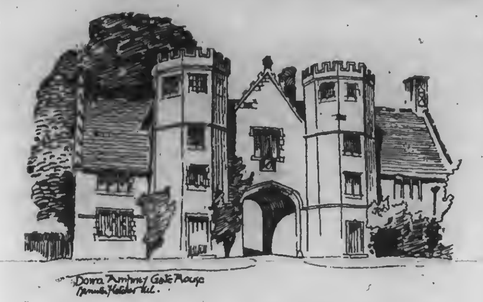
Besides being valuable for house construction, the material is available for use in the construction of sewer pipes, electric wire conduits, and water-mains. In art and decorative work it is also expected to be of use.

Professor Brown owns a piece of material which he says is known to have been taken out of a building erected 1,500 years ago, and he declares it to be the same as this new compound.

PERSONAL.

Mr. Edward Harrison, Jr., of Topeka, Kansas, chief of the engineering staff of the Santa Fe Railway, has been visiting Hamilton, Ont., his old home, after an absence of thirteen years. He was once a student in the office of Mr. James Balfour, architect.

Mr. D. Ewart, chief architect of the Public Works Department at Ottawa, has recently returned from Europe, whither he went for the purpose of investigating fire proofing materials and methods. He is reported to have expressed the opinion that none of the systems which he examined while abroad are in any respect superior, but are rather behind the methods in use in Canada.



SEWAGE DISPOSAL IN SUMMER RESORTS.

The following report presented to the Provincial Board of Health of Ontario at its last session has appeared very opportunely, and in large measure supplies an answer to problems raised in an editorial in our last number. The several suggestions made in the report are simple and inexpensive and have the merit of being practical, having been carried out as the report states in many instances under the personal supervision of Dr. Bryce. We hope to obtain from the writer individual illustrations of places where these are in operation.

REPORTS ON SEWAGE DISPOSAL IN SUMMER RESORTS AND TOWNS WITHOUT SEWERAGE SYSTEMS.

By the Secretary, Dr. P. H. Bryce.

Mr. Chairman and Gentlemen:—The disposal of organic wastes becomes, with every summer, during which decomposition under the influences of heat and moisture have gone on most rapidly, a question which every layman and physician are prepared to discuss, but which with the incoming cold weather, is allowed to remain unsettled and debatable.

When it is remembered that on the shores of the lakes and rivers adjacent to every city and town, and notably in certain districts favored either by nature or railway conveniences, many thousands of people make their summer homes in temporary structures, as tents or in small cottages, and that the two questions of a pure water supply and the disposal of house wastes are constantly associated, it is apparent that some very positive opinions should exist on the part of campers and householders as to what ought to be done, and can be done economically, and yet more positive views as to the need of regulating such resorts on the part of the officers and local boards of health.

Without dealing at length with theories of disease causation, it may at once be said that experience has positively shown that water into which animal matters pass, whether stream or lake, or by soakage into a well, cannot long be used for domestic purposes without causing diarrhoea, enteritis or typhoid. Not a day passes at this season, in which well and other water, used in houses where typhoid is present ; are not shown by the laboratory to have pathogenic microbes, whose habitat is the intestines of men or animals, present in them. In the great number o instances, at summer cottages and camps, there are but two sources of trouble, viz., house slops and kitchen refuse, and human excreta. Hence I propose to give as briefly as possible, what years of experience have proven to be a simple, efficient and relatively a inexpensive means of safely dealing with these several wastes.

Ordinary human excreta is very easily disposed of by the earth closet, placed conveniently to the cottage or camp, and having galvanized pails of good capacity used, to which leaf mold from the forest, sawdust, dried garden clay loam or peat, may be systematically applied, which will prevent all odors due to decomposition, through absorption of gases from the decomposing excreta. Such materials should be frequently removed and dug into the garden in a shallow manner, just as manure is for fertilizer. No inconvenience can result, the garden is enriched and no one portion earth need ever be saturated with organic matter.

The same method of disposal by trenching is equally available for kitchen refuse from which the watery portion has been removed in the following manner.

An ordinary oak barrel of 20 gal. capacity, or a galvanized iron bucket of similar capacity, is placed convenient to the kitchen door, into which all slops, solid and liquid, will be placed, the watery portion being separated as seen in the diagram by a removable pan with perforated bottom. A

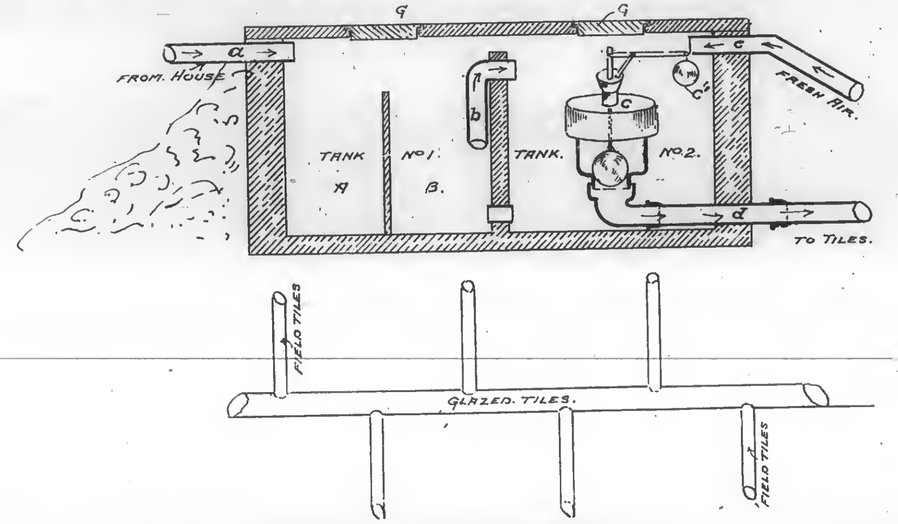


DIAGRAM NO. 1, FOR DISPOSING OF KITCHEN WASTES.

kitchen sink may, if preferred for convenience, discharge its watery contents directly to the barrel and the day refuse be there separated. From the diagram, it is apparent that liquid slops will be retained in the barrel until by a float or by observation, the barrel is filled up to the pan with perforated bottom. All that is then required is to draw the plug and allow the liquid contents to be rapidly carried away to the level subsurface tiles. A tight-fitting cover will effectually prevent any local nuisance from arising, while the tiles which are an example of intermittent downward filtration, (see Diagram 2), will have allowed the watery portion of the slops to filter away, the smaller amount remaining, undergoing decomposition, its gases being absorbed by the surrounding soil. It will be apparent that if the tiles laid,

hold exactly the contents of the barrel and are laid level with its bottom, that each will be filled with each discharge and hence will become in practice never clogged equally as those near the barrel would, if the liquids were allowed to trickle away without any pressure. The tiles, if within a foot of the surface, will readily obtain the oxygen necessary to decomposition through the soil.

It will thus be seen that for a small temporary summer dwelling with a well, spring or lake supply of pure drinking water, everything has been provided to maintain perfectly sanitary surroundings.

Inasmuch, however, as year by year these summ dwellings are being occupied for longer periods, as many summer houses are becoming large, well constructed houses with every modern convenience and water pumped by machinery, and as hotels with a capacity for hundreds of guests are springing up in isolated situations and thousands of farm homesteads are demanding modern conveniences, it is apparent that more extended methods are necessary for disposing of house wastes, so that water supplies may not be polluted, and local nuisances be prevented.

In past years, cess pools or deep pits in the soil have been used as receptacles ; but inasmuch as the soakage therefrom becomes often an excessive local pollution, endangering well water, and as they, sooner or later, become filled, other means are demanded for dealing satisfactorily with the house sewage, which, in the case of hotels and large institutions, makes thousands of gallons daily, and contains all the wastes, whether excreta, kitchen or house slops.

Fortunately the application of the same principles as already indicated for dealing with small houses are equally applicable in dealing with larger establishments. Many towns have public water but no sewerage, and owing often to the large lots and relatively widely separated dwellings, public sewers would prove an expensive matter. In all these cases the following methods have been found economical and from the sanitary standpoint, most satisfactory. The bacteriolysis of sewage or its decomposition, like manure in the soil, by the bacteria of nitrification has to-day taken its place as the most practical and scientific method of disposal of sewage known to us. It is especially satisfactory in dealing with purely domestic sewage apart from manufacturing wastes. The first essential in establishing any such system is to have the plumbing fixtures so placed as to bring all the pipes to the iron soil pipe, which is the main sewer from the building. This, brought out below the ground floor, is led to a tank, built either immediately at the house, or at such convenient spot away from it, as will enable the sewage effluent to discharge from it and to flow into a series of field tiles laid on a level with the bottom of the tank at a depth of 10″ to 12″ below the surface of the ground. Should such main iron pipe be above the ground, it can be placed on supports, or be laid on a ridge of earth covered with sod. Much discussion has gone on as to whether sewage is best dealt with by aerobes, anaerobes or both ; but to-day it may be said to be perfectly accepted that microbes which derive their oxygen from air, and those which obtain it from organic compounds, are both required to rapidly and effectively decompose or nitrify sewage. This may be done by the construction of a tank, or several tanks for different wings or portions of the building as simply made as that in the following diagram :

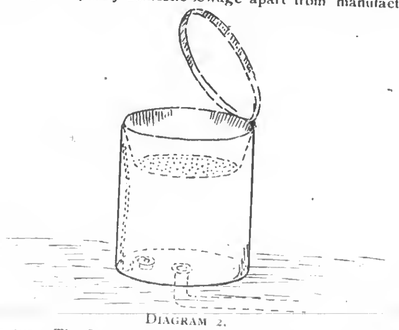

DIAGRAM 2.

The diagram shows the inlet of sewage at (a) from the house main to tank No. 1, which has two compartments separated by two planks simply laid, one above the other for lessening the amount of solids in compartment B. From this, watery sewage passes over into tank No. 2, through the pipe (b) from under the mass of semi-solid floating sewage undergoing fermentation and held up by the gases thereof. At the bottom of tank No. 1 a carbonaceous sediment gradually, but slowly, accumulates, and may occasionally be removed. The liquid sewage in tank No. 2 contains the ammonia gases, either free or combined as ammonium carbonate. From this tank to the extent of its whole contents, whether 50 or 1,000 gallons, is discharged by an automatic flushing valve, (c) when the tank fills to any level while the adjustable float (c^1) is set as required. Syphons especially made for different depths of tank are equally available for this purpose. The effluent passes into a series of field tiles (d) carefully laid on a level some ten inches beneath the surface of the ground, exactly sufficient in number to hold the amount of sewage discharged. Fresh air is constantly supplied through the inlet, (e) which not only assists bacterial growth, but being colder causes an upward movement of cases through the house soil pipe. The tanks may be entered by manholes (G) and the double cover of tank may, if it be found necessary to prevent odors, be covered with soil or sodded with loam if the location be in a cultivated garden.

The extent to which this system may be utilized can be understood when it is seen that with carefully prepared levels a series of terraces may be arranged, each having its series of pipes on successive levels, supplied from a single main carrier, in which the sewage passes from terrace to terrace, by small wells at the edge of each, this enabling the field tiles to be kept near the surface.

It is of course apparent that as the nature of soil varies, it is desirable, if possible, to utilize sandy or porous soils ; but in experience it is found that with frequent deeper sub-soil drains at a depth of three feet, even clay soils prove amply sufficient for ordinary houses. It may happen, as in Muskoka, that a house is placed on a rocky site and no land near by is available. In such instance it becomes necessary to make an artificial sand or fine gravel filter, beneath which the field tiles are laid. This, in several instances, has proved quite satisfactory.

What seems most desirable is that the local Boards of Health should become better informed on these methods of disposing of the liquid refuse or sewage from houses, stables, slaughter houses, cheese factories and other manufactories, since, in our experience every year, a large amount of correspondence with the Board takes place regarding effluvium nuisances and pollution of well waters, which could be wholly avoided if such a system were in use. The distribution of a special pamphlet on this subject would seem especially demanded.

THE AMERICAN INSTITUTE OF ARCHITECTS.

The able address of Mr. Robert Peabody, President of the American Institute of Architects delivered at the opening of the recent annual convention in Buffalo, contains many valuable suggestions for the guidance of that body and its individual members as well as architectural societies and architects everywhere. Lack of space prevents its full publication, but a few of the principal points developed may profitably be noted. The necessity of making proper preparations to meet the demand for a high standard of artistic work, consequent upon the growing wealth of the nation, was referred to. To this end the association of a number of architects together in practice was commended as a better than the individual method.

The advance in architectural education was noted as being another important step in the direction of producing a class of architects fitted to meet the demands of the present and future. The education necessary to this purpose could best be obtained in the most perfectly organized architectural schools, and the duty of the Institute was to foster the work of these institutions. The founding of a prize in charge of the Institute for competion among graduates of these schools was suggested.

The value of draughtmen's clubs as a means of education, and as feeders to the Institute was dwelt upon. Under this head Mr. Peabody said :—" I suggest referring to a committee the question whether an alliance cannot be made either with the Architectural League of America or an association like it which might become the instrument of the draughtsmen and younger architects. I would make it the centre for classes and club life from which the older members, as they recognize that their turn is past, would naturally graduate to the Institute. To their hands, when the proper time comes, we should gladly bequeath the American Institute. If, to-day, our youths are apt to think that in this or that case the duties of the Institute have not been properly performed, it will be their turn then, and I trust that they will do far better than their predecessors, who had no Architectural Leagues in which to prepare themselves for their work." The address closed with the following reference to the work of the Institute : " We can only measure the amount of good the Institute has done by its output. Many a man who cares little for it benefits because others have cared. Many a man outside of our numbers is more respected in his community and has a more certain livelihood because the Institute has proved itself a reasonable public body. Certainly, through its influence, the perils and hardships of competitions have been greatly mitigated. But all these are small and selfish ends. The real value of the Institute lies in its opportunities, in its openings for useful work and mutual high endeavor. Thanks to the wisdom of its founders, I think it has been a potent means of good. Thanks to them, it has none of the features of a selfish trade union. In a trade union a man's powers and skill are handicapped for the general good ; but with us a member has entered into no engagements of any kind except that he will honorably practise his profession. Our compact is rather that of the ancient guilds, into which no one could enter who was not a master workman. We seek to make membership a sign of established character. We are trying to make it impossible for anybody to be an Associate who has not thus established a name for honorable professional conduct, and for no one to be a Fellow who has not done really distinguished work. With the coming year, entrance to the Institute will be possible only through examination arranged by the Institute, or on presentation of a degree from an accredited School of Architecture. I believe that the new tests will cause large additions to our numbers, because Associate membership henceforth is to mean that a definite and valuable standard of skill has been reached, and that from among this membership their comrades are to choose by honorable election the Fellows of the American Institute of Architects. To many young men these will, I doubt not, seem valuable inducements."

TORONTO ENGINEERS' CLUB.

At the regular meeting of the Engineers' Club of Toronto on October 1st, the topic for discussion was " Parks, Squares and Drives for the City of Toronto." It was expected that Mr. Cecil B. Smith would introduce the subject, but owing to business engagements he was unable to be present. The president, Mr. Hertzburg, expressed his interest in the subject, and referred to the plan proposed by the Guild of Civic Art, which was that some general scheme should be followed in future in the laying out of public parks and streets. He was in favor of diagonal streets. Mr. Spry did not think that Toronto was capable of much beautifying, as it was laid out on an ugly plan. He thought one of the greatest drawbacks was the impossibility of obtaining a good view of even the largest buildings in the city. Neither were there any suitable sites on which to place statues or anything of that kind. Mr. Chipman said that it would be very expensive to open cross streets, but that this might be kept in view in future extensions. The improvement of the harbor was referred to, the consensus of opinion being that it would be difficult to carry out any plan of improvement unless at considerable expense. Mr. Spry advocated the concentration of all heavy freight at one end of the harbor. Mr. A. B. Lambe said that in his opinion it was a question of beauty versus utility. He did not think the commercial interests should give way to parks and squares. The advisability of placing the sidewalk next the curb was discussed, opinion being about equally divided. Finally a resolution was unanimously adopted approving of the suggestion of the Guild of Civic Art that in the laying out of future streets and squares a general plan, which would eventually produce an artistic and harmonious result, should be adopted.

CANADIAN ART.

The Pan-American Exposition has brought conspicuously to public attention a phase of American art that has been developing slowly and surely, but without so much as a passing notice of its existence. I mean the work of Canadian artists.

The art exhibition of the provinces in the Albright galleries is not extensive—only forty-nine artists are represented by eighty pictures—but the collection is eclectic in the best sense of the term, and it is thoroughly representative of the best efforts of the Canadian painters. Fully half the contributors are connected with the Royal Canadian Academy, whose members, through their officers, Robert Harris, G. A. Reid, M. Matthews, and James Smith, have taken a commendable pride in showing the highclass of work now being done in their country.

We, in the United States, with our larger and broader art interests, are apt to overlook, and perhaps even disparage, the art products of the Canadian provinces. Many readers, doubtless, do not even know that there is such an institution as the Royal Canadian Academy, and those who know of its existence perhaps fail to realize that in the measure of its opportunities this institution is striving zealously to stimulate and broaden the art spirit in Canada and to promote every form of art interest.

That the work of the Academy is attended by difficulties and discouragements is frankly admitted by the officers of the institution. It is chiefly in the provinces of Ontario and Quebec that one can speak of an art spirit at all. Many of the best artists of these provinces have of recent years left the country, lured by what they thought were the brighter prospects offered by the populous cities of the United States. The market for high-class work in oil and watercolors in Canada is narrowly circumscribed, and as a consequence there has been a tendency for years toward the depletion of Canadian studios. The artists move away and soon are utterly lost to their country, since change of residence has in most cases involved the assumption of new allegiance, the artist claiming little more than Canadian birth.

The same is true of those who have made illustration a specialty. The publishing interests of the provinces are meager and can give but scant employment to promising men. In consequence there are probably fewer competent artists in Canada to-day than there were a decade ago.

Canadian artists have the same complaint as their American confreres, that the collectors and connoisseurs of their own country, who spend thousands of dollars annually in works of art, are prone to slight native talent and devote their money to the purchase of Old World products by recognized masters. This, however, is less surprising than in the case of artists of the United States. As was recently pointed out by one of the closest observers of Canadian art interests —and a Canadian himself—it is only of recent years that the art of Canada has passed beyond the production of fairly well executed water-colors depicting still-life subjects or topographically correct bits of landscape.

It is not to be overlooked—and the fact should be noted in justice to the public—that those Canadian collectors who have expended large sums for foreign art works have felt a sense of obligation to foster home talent and have been the most liberal patrons of the colonies. In a word, Canada has been in the position of most colonies the world over. It has received slight and patronizing recognition from Englishmen in general, and virtually no recognition from the residents of other countries. Under these circumstances, it is somewhat surprising that native artists have made

such satisfactory progress. In reviewing the development of Canadian art during the last decade, M. L. Fairbairn said recently :

"Our national art institution, the Royal Canadian Academy, during these ten years has pursued the even tenor of its way, filling the vacancies made by death or removal, holding its yearly festival, staid, respectable, slowly progressive, adding to the permanent collection in Ottawa the diploma of its new members. The number of exhibits each year has not increased, because in former times each academician was entitled to have twenty pictures hung, no matter what their merits, so the walls were always covered. The number has since been reduced to ten, and later to eight. The standard for the works of outsiders has been raised, so that with fewer pictures the exhibitions are better."

The same characteristics that Mr. Fairbairn speaks of as obtaining in the last Canadian exhibition are observable in the exhibit at the Pan-American. Canadian painters have been brought under the influence of all the art influences of recent times. This is partly due to the fact many of them have received instructions from masters in leading schools outside their own country and partly to the practice of importing and

Canadian Art Exhibit.—Pan-American Exposition.

exhibiting in the leading cities of the provinces examples of the best work of American and European artists. Canadian artists have thus fallen into line in all new movements, following instead of leading, it is true, but nevertheless giving evidence of an alertness to what is going on in the art world to-day and a desire and a capacity to profit by the examples which they have not yet been able to set.

This is conspicuously shown in the work of the various art schools throughout the provinces. These schools are increasing in number and efficiency, and they find an able auxiliary in the Women's Art Association, which has developed with remarkable rapidity during recent years, and which now has branches in a number of the leading cities throughout the provinces of Ontario and Quebec.

Interest in the art work of the better known schools is also markedly advanced by the development of an arts and crafts movement in Canada. Lovers of the beautiful were not slow to take inspiration from William Morris, who sought to apply art to the requirements of daily life. The direct result of Morris's influence has been to impel Canadian artists to supply designs for the manufacturers of their own country and to inaugurate various exhibitions of applied art and design. A higher standard of taste has thus been developed as regards both fine and applied art, and this higher standard of public taste, for which the artists themselves are responsible, has reacted upon themselves and of necessity impelled them to higher attainments.

The Canadian art exhibition at the Pan-American shows the fruits of this healthful condition of affairs. Of the eighty pictures displayed, many are of an exceptionally high quality, showing broad, truthful treatment and mastery of technique. William Brymner shows three charming water-colors, two of which, "The Gray Girl" and "Francie," are finely executed figure-studies. "The Gray Girl" presents a little miss in the attitude of writing, and "Francie," portrays a sunny-haired child standing in natural posture against a dull gray background. In both pictures the color scheme is low-toned, harmonious and eminently pleasing. F. M. Bell-Smith also displays three characteristic pictures, "London Bridge," "Strawberry Pickers" and "Above the Clouds." These show a wide range of interests, and a capacity for different types of work that augurs well for the future of the artist.

J L. Graham's three pictures, "Dinner-time in a Stable," "Ploughing," and "Carting Sand," show a marked ability to invest homely scenes with poetic character. His "Carting Sand" depicting two horses pulling a load over a heavy road, with a couple of countrymen walking beside the wagon, is an especially worthy interpretation of country life. Robert Harris, president of the Royal Canadian Academy, who won a medal at the Chicago exhibition. and also an honorable mention at the Paris International Exhibition a year ago, exhibits two fine portraits of women, suggestive of a close study of Gainsborough.

In the line of portraiture, E. Dyonnet, E. Wyly Grier, who took a third medal at the Paris salon, A. D. Patterson and G. A. Reid also exhibit fine canvases, which betray a delicate palette and a firm grasp on the essentials of good portraiture, "The Beach of St. Malo," by James Wilson Morrice, is especially pleasing in tone and subject, as is also "Girl Knitting," by Laura Muntz, in which sunlight effect is most admirably depicted.

G. A. Reid, also a medallist at the Chicago Columbian Exposition, exhibits a choice decorative panel, "Summer"; F. M. Knowles, two fine picteres of the Thames River and an equally choice canvas, "The Last Load"; William Cruickshank and F. S. Challener, familiar farm scenes ; M. A. Bell and John Hammond, marines ; and H. Blair Bruce, a dainty canvas depicting nude maidens sporting on a moon-lit beach.

Other canvases are no less worthy of mention, and space alone forbids further specific mention. Suffice it to say that W. E. Atkinson, J. A. Brown, Henri Beau, W. D. Blatchly, F. H. Bridgen, Maurice Cullen, Florence Carlyle, J. W. Forster, J. C. Franchere, R. F. Gagen, C. S. Haggerty, Homer R. Watson, Mrs. Mary Heister Reid, Edmund Morris, C. J. Wray, F. A. Verner, William Hope, M. Matthews, and other leading artists of the provinces are represented by pictures ranging from still-life to landscape, and from portraiture to genre subjects. These pictures do not suffer by comparison with the work of other American artists.—Katherine V. McHenry in Brush and Pencil.

ONTARIO ASSOCIATION OF ARCHITECTS.

The Toronto Chapter of Architects have arranged with the authorities of the Toronto public library to allow books from the valuable collection of architectural works in the library to be placed on the tables in the Association Rooms on Tuesdays, so that they may be inspected by architects attending the weekly luncheons.

A CANADIAN ARCHITECT IN KOREA.

The friends of Mr. H. B. Gordon, of the firm of Gordon & Helliwell, architects, Toronto, who left Toronto in June last for a temporary residence in Korea, will be pleased to learn of his safe arrival and good health. Korea, as our readers are aware, is a peninsula jutting out from the northern part of China. The capital, in which Mr. Gordon makes his headquarters, is Seoul. Here is the centre of the missionary work in Korea, conducted by the American Presbyterian Missionary Society, in whose employ Mr. Gordon is at present, having been commissioned to design and superintend the erection of a number of buildings for the Society, including a hospital and houses for the missionaries. Mr. Gordon writes that sketches of several of these buildings have already been prepared, but not finally approved. He is at present in China in connection with proposed improvements to the Society's property there. Of the native architecture of Korea, as represented by the hotel in which he is quartered, Mr. Gordon writes as follows :—

"The hotel is a one story Korean gentleman's house built in Korean style. The compound is enclosed by a wall and has a gate house—nothing very stylish. The buildings consist of the main part built around a court or garden and the servants' quarters built out separately. The walls are a strong frame resting on stone work, and the spaces in frame filled in with 4½ inch brickwork in two colors, viz., red and dark grey. The roof is the strangest and strongest combination of posts and large beams, with rafters made of round beams, covered with small pieces of wood and about 6 ins. to 1 foot of mud, and then roofed with tiles. The spaces between the rafters and the inside walls are plastered and then the whole thing papered. The house looks quite picturesque from the outside and very quaint within. There are very few two story buildings here, except the foreign houses and the palaces. It is not considered etiquette for a common man to live in a two story house."

KING ALFRED WAS AN ARCHITECT.

The Manchester Society of Architects have presented to the Free Reference Library of that city a chaplet to be hung below the statue of King Alfred, accompanied by the following explanatory notes by the president : "It is not generally known, perhaps, that King Alfred was an architect. William of Malmsbury, in his 'Chronicles,' speaks of him as 'not only a lawyer, uler, mathematican and poet, but also a complete architect.' Of course we know that he rebuilt London, and also really built the towns of Winchester and Dorchester. He was, in fact, a real architect as well as a great many other things. It struck me, as President of the Manchester Society of Architects, that it would be a nice thing to honour his memory, and the society has sent the chaplet, which is made of laurels to indicate his victorious character, and white flowers to indicate his high morality. The society declared that the chaplet should be accompanied by the statement that it was from the President of the Manchester Society of Architects as a token of high respect for the memory of the great monarch, who was the pioneer of English architecture."

A correspondent writing from the newly opened district of Temiscaming in Northern Ontario, states that deposits of a peculiar blue clay have been discovered suitable for brick making, as well of clay specially adapted to the manufacture of pottery and sewer pipe. It is said that capital is being raised with which to establish a pottery.

BOOKKEEPING FOR JOINT STOCK COMPANIES.—A practical and comprehensive treatise on the organization forms and bookkeeping entries required to meet the varying conditions of Joint Stock Companies of all kinds, together with an analysis of the Dominion and Ontario Acts governing such corporation, by David Hoskins, Chartered Accountant, Principal of British American Business College, Toronto, and Vice-President of the Institute of Chartered Accountants of Ontario. Published by the Federated Business Colleges of Ontario, Limited, Toronto, Price, $1.50.

The author of this work has, we are pleased to see, avoided the error into which most writers of bookkeeping texts have fallen, namely, that of arranging the matter in such a way as to necessitate a large amount of mechanical work being performed before any practical benefits can be obtained; on the contrary, his explanations are so clear and concise and so excellently indexed that the busiest of men can obtain full information on any of the many technical points of joint stock company bookkeeping or law, in a surprisingly short time. The whole subject has been treated in a thoroughly practical and business-like manner and shows a masterful grasp of the entire range of company accounting. The chapters dealing with the conversion of business concerns into Limited companies and the Amalgamation of Companies are particularly good ones, while the many illustrations of Financial Statements used by the leading Canadian mercantile and manufacturing institutions cannot fail to be of great value both to the business man and the accountancy student. A first-class idea, in this book is that of including the questions set on the examinations of the Institute of Chartered Accountants of Ontario. Mr. Hoskins is to be congratulated on his important addition to accountancy literature.

If you are looking for a high grade Finish for Floors

Granitine Floor Finish

Is unsurpassed in Durability and Beauty of Finish for Natural Wood and Parquette Floors, Linoleums, Oil Cloth, Cork Matting, &c.

Its transparency reveals the grain of the wood, and its preserving qualities increase the life of the floor.

Its sanitary properties are highly commended, as it closes thoroughly the pores of the wood against disease germs, and permits the floor to be kept thoroughly clean.

It is easier applied, more durable, makes better finish than wax preparations, and is free from all unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks; nor does soap, mud or water destroy its fine appearance.

Manufactured only by

TORONTO, ONTARIO, CANADA.

"LINCRUSTA WALTON AND CAMEOID."

A visit to the show rooms of Messrs. Fred'k. Walton & Co., Limited' No. 1 Newman street, London W., patentees and sole manufacturers of above well-known material, is always a source of both pleasure and profit. It is well said that an Englishman's home is his castle. Messrs. Walton have done much in recent years to enable the public to make their homes beautiful and artistic at little cost. One very important feature of "Lincrusta Walton" is that it can be fixed to any surface and will stand any climate, and the fact of it being absolutely solid both in color and relief, enables it to be placed on walls which are subject to heavy traffic and hard wear. "Lincrusta Walton" CANNOT WEAR OUT, and when properly fixed will last as long as the building it beautifies. It is worth remembering that this material can be made in almost any color to order, solid throughout, this being a decided advantage for a hurried job, besides saving the cost of painting. Cameoid is the latest material in high relief for walls and ceilings, and the Company may well claim that for lightness in weight and firmness of relief this decoration cannot be excelled. The works are now busy preparing many new and important designs for season 1902, which will be ready shortly. To meet the rapidly increasing demand for cheap embossed materials, Messrs. Walton have a very useful selection of low relief patterns in Cameoid, from 6d per yard.

Foundation Bricks. *Stock Bricks.*

Examine our Foundation Brick before specifying stone. A cordial invitation is extended to visit the yard.

WORKS, DON VALLEY. OFFICE, 34 TORONTO STREET, TORONTO

Combination Union Valve Elbow

Patented January 30, 1900

For Hot Water

Is more elegant in design than a Valve or an Elbow. It is quick opening (Qr. turn) and adjustable to either end of the radiator. It has a true curved, full sized water way which reduces friction. It is neatly and compactly made of valve metal and packed ready to use. It has rough body, with finished trimmings and is nickel plated all over.

Operated with the foot. Costs no more than a valve. Every one warranted.

THE ROBERT MITCHELL CO., LIMITED - MONTREAL

Sold to the Trade Only. *Sole Licensees for the Dominion of Canada* *Send for Discounts.*

NOTES.

A combination is said to be in process of formation to control the worlds' supply of window glass.

Contracts aggregating about $11,000,000 for construction work on the buildings and grounds of the Louisiana Purchase Exposition will be awarded about December 1. About $7,000,000 of this amount will be expended on the buildings and about $4,000,000 on the grounds. The first contracts to be let will be for the four big exhibit buildings which, with their surroundings, will, it is estimated, cost about $4,000,000. The main buildings will be larger than those of any previous exposition in Europe or America. Some will exceed similar buildings at former expositions by over 25 per cent.

Official intimation has just reached Mr. Edwin O. Sachs, chairman of the British Fire Prevention Committee, that a large silver portrait medal accorded by Her Majesty, the German Empress, in connection with the Fire Congress in June last, has been presented to the Executive of the Committee as a mark of appreciation for the services rendered by that body in the demonstration of scientific and economic aspects of fire protection. It will be remembered that a deputation of the committee comprising Mr. Edwin O. Sachs, (chairman), Mr. Ellis Marsland, Mr. F. R. Farrow, and C. E. Goad, accompanied by the secretary and engineer, visited Berlin in the summer, and that an important exhibit of technical models and photographs was loaned to the German authorities for the exhibition held in connection with the Congress.

LEGAL.

In reply to a correspondent the American Architect states that unless an architect copyrights his designs, the law will not prevent the client for whom they were prepared and who has paid for them, from giving copies of them to his friends. The general tendency of judicial decisions in the United States courts is said have been against the establishment of implied copyrights of any kind.

ACADEMY OF ARCHITECTURE AND BUILDING.

1742 Chouteau Ave., St. Louis.

An institute for the technical education of buildi g tradesman and draughtsmen. Students may commence at any time. Graduates are assisted in obtaining po-itions as draughtsmen, superintendents, foremen, etc. LESSONS BY MAIL, for home instruction. Send 25 cents in stamps for a useful book of interest in self-instruction. Mention the CANADIAN ARCHITECT wheo writing.

Montreal and Toronto.

FIRE-PROOF GLASS WINDOWS THAT ARE FIRE-PROOF

These windows in a fire-proof building, complete the security, and in any building will thoroughly prevent the spread and advancement of the fiercest flames.

Better than iron shutters (even if they happened to be closed at the needed time); fire-proof glass remains intact, resisting both the intense heat of the fire and the action of water.

Many practical tests have proved it's efficiency.

Used in conjunction with our hollow sheet-metal frames and other fire-proof fittings, it gives the most perfect protection available.

It's adoption lessens insurance rates.

If you want to know more about "fire-proof windows," write us, it's an interesting subject.

Safety of Elevators. An elevator in one of the principal office buildings in Toronto, dropped twelve or fifteen feet the other day. The suspension cables became detached from their fastenings at the top of the shaft and fell in a heap on the cage. The passengers fortunately escaped injury, but as may be imagined, were badly frightened. Rumors are abroad of similar happenings at some of the great departmental stores of which no mention has appeared in the papers. A system of elevator inspection is supposed to be in force in Toronto, but these accidents would seem to indicate that its efficiency might and should be improved.

Methods of Designating Floors. So much confusion exists regarding the order in which the different floors of a building should be named that some leading Canadian architects have decided to fall in line with American practice and the ideas of the majority of their clients by numbering the different floors one, two, three, etc., beginning with the ground floor as number one. The practice here and in England has been to name as the first floor the one first above the ground floor. It is claimed, however, that probably 75 per cent. of architects' clients regard the ground floor as being the first floor. The result is frequent misunderstandings between architects and clients, requiring frequent explanations, and leading to delays where matters have to be arranged by correspondence. It is thought by some that the difficulty would be overcome by adopting the American instead of the English method. Where there are basements, the floor would be designated as the "basement floor," and the floor above as the "first floor," counting from the fron of the building. Local architects are by no means unanimous in opinion regarding the advisability of changing the method which has been in vogue until the present. The subject is an interesting one and of considerable importance to the profession, and might profitably receive discussian at the Annual Conventions of the Architectural Societies.

Workmen's Compensation Acts. The Workkmen's Compensation Acts of Canada, fashioned after the law of Great Britain, are found to be not less difficult of interpretation. In Great Britain all sorts of interpretations have been given by the Judges of the various courts, resulting in such a legal muddle, that there appears to be no certainty in the mind of anybody as to what an employer's liability under the act really is. As evidence that the meaning of the Canadian law is equally obscure, it might he mentioned that the partners of a well-known legal firm not long ago spent half a day in discussing the interpretation of a particular clause. Much unnecessary litigation as well as injustice seems certain to be the result of the operation of this important law simply because proper care was not exercised in its construction.

The Designing of Factories. Architects and persons interested in architecture outside of the profession, will rejoice to observe the more or less successful attempts that are being made to give a character and interest to the design of factory buildings. Such buildings need not necessarily look like huge packing boxes. They may be well adapted to their purpose,

and kept within moderate cost, while at the same time showing character in design which will make them attractive and interesting to the beholder. In striving to secure this result, however, architects should be careful to see that the purpose which the building is intended to serve is expressed in the design. No doubt the reader has seen, as we have, factories which looked like public libraries and water works, pumping stations that had the appearance of banks.

A Prosperous Season. The building season now drawing to a close has in most localities, and particularly in Toronto, been marked by unusual activity. From Winnipeg in the west to Sydney in the east, building improvement has been advancing rapidly and on a large scale. This activity is the reflex of the commercial prosperity which is at present everywhere visible, and which it is gratifying to know shows no signs of abatement. The building industry, which so intimately depends upon sound financial conditions, seems likely to enjoy a further period of prosperity. The rapid growth of our manufacturing industries has necessitated the erection of many new factories throughout the country, and these have resulted in improvements in other directions. For example, as the result of the introduction of beet growing and beet sugar factories, land in some towns in Western Ontario is reported to have doubled in price, and many new buildings will be the outcome of the increased stimulus which these towns have received. In Toronto, in addition to the large new hotel on King street, several new banks and insurance buildings have been erected and a large amount of residency work of good character has been done. With few exceptions the architects have had their hands full of work, and in some instances have found great difficulty in procuring office assistants, which, as already stated, indicates that the season has been an unusually busy one all over the Dominion and continent. The increase of population in Toronto has wiped out the effects of the overbuilding done a few years ago, so that houses are in steady and urgent demand. Desirable office accommodation is also at a premium, and the coming year is likely to witness the erection of one or more large office buildings.

Heating Methods. Great improvements have been effected in recent years in apparatus and methods of heating buildings. By means of various present day systems it is possible to maintain an equable temperature of say 70 degrees throughout all parts of a building with the outside temperature at zero, thus ensuring a high degree of comfort in winter even in a cold climate. The ideal condition will not have been reached, however, while coal continues to be employed as fuel, involving as it does so much labor. The inroads which electricity has made as a competitor of gas for interior lighting, has induced the gas companies to encourage the use of gas for cooking purposes. So profitable have been the results in this direction that the loss of a large lighting business is regarded with a degree of complacency. It is to be hoped that the gas companies will go a step further and furnish the means whereby gas could be used instead of coal for the heating of buildings. At present every building is a gas works on a small scale, having in the basement a furnace and system of pipes and a pile of coal with which to produce heat. How much better it would be to have the gas produced and supplied ready for use from a central station, as in the case of illuminating gas. In view of the constant reduction in demand for illuminating gas, it may eventually be that the gas companies will supply gas of a lower grade for heating and cooking purposes, which by means of apparatus on the premises can be so enriched as to be also adapted for lighting when required.

The Commercial Age Commercialism is stamped upon almost everything to-day, This age will probably be known in history as the Commercial Age. The people generally are so engrossed in money-making that the accomplishment of great things in other lines is scarcely to be expected. Almost every article used or worn is made by machinery, much of it by automatic machinery designed to produce the greatest quantity with the least expenditure of time and cost. The occupation of the skilled workman is to a large extent gone. Young men with original ability to make good carpenters are put to feed a machine, and as a natural result in time themselves become machines without the ability to devise or execute any work requiring the use of either brains or skill. May we not expect that after two or three generations of such men shall have passed the standard of intelligence and ability will have sunk to a deplorable level? Already complaint is heard from architects and builders of the difficulty of securing skilled workmen capable of doing the finer and more important features of their work. One after another the older workmen trained in Europe are dropping out of the ranks, and none are found qualified to succeed them. Opportunity is no longer afforded youths of acquiring knowledge of a trade. In the shops and factories of to-day the work is specialized to the greatest possible degree, and machinery employed wherever possible. Everything is sacrificed to cheapness of production and individuality, ambition and skill on the part of the workman finds little encouragement. Is it any wonder that there is so much that is not genuine in the construction and finishing of modern buildings? The stores are filled with shoddy goods; for example furniture, which is a cheap and nasty imitation of honest wood and covering which could not be sold for double the price. The taste of the masses of the people is being perverted, and they are encouraged by means of these cheap and showy wares to enter into foolish and ridiculous competition in mode of living with their neighbors and people with larger resources. Out of this competition has sprung the instalment plan stores, which are the worst offenders against frugal and common-sense living. It is undoubtedly true that the cheapened cost of production of many articles due to the increased use of labor-saving machinery has placed these articles within reach of and added to the comfort of the masses. Against this, however, must be placed the degeneracy of the artizan and the perversion of taste already referred to.

Mr. Andrew Carnegie is said to have given away up to date the sum of $11,254,500 towards the erection of public libraries.

The funny man of the Toronto Star rises to remark that those new elevators in the parliament building will be used when they wish to give a measure the six months' hoist.

Mr. Thos. M. Morgan, whose cement works at Longue Point, Que., were recently damaged by fire, claims that the concrete walls built two years ago came out of the fire almost intact.

NOTES OF A VISIT TO BOSTON AND NEW YORK.

My journey had no professional motive; but, where there are so many good buildings, one cannot fail to have noticed something worth reporting in notes such as the Editor wishes me to make.

I broke the journey at Albany both going and returning. Besides other reasons, there are two points about Albany that make it interesting to a Toronto person. It is situated on a hill and it is built in rows. To sit at breakfast in my hotel and look out upon a steeply ascending street, with all the variation that this implies in base and sky lines, was in itself a treat to one accustomed to see everything on a dead level, but in the streets themselves, closed at the bottom with a view of the hills across the Hudson and crowned with the State Capitol, the beauty of a city set on a hill was still more apparent. As to buildings in rows, I must confess to a liking for it. A city is a city when it is built solid, and dignity is so much more easily attained. When there is only one front, the expense of good material is compassable. Even with plain material success is easy. Then the convenience! There are no distances. The best residences are from five to ten minutes from the shops, and the best shops are all together in a block or two. One can do in Albany in less than an hour what would take a morning to accomplish in Toronto. The Capitol is five minutes from the railway station, the Park fifteen; there is nothing beyond, and one includes the shops on the way to the Capitol. Yet Albany has a population of 95,000. So much for compactness in a city.

This note is not without application in a city which, like Toronto has grown so far beyond the limits of convenience that a consolidation of residences within the region of the Belt Line would be a great gain.

There are many interesting things in Albany. The Capitol and City Hall are well-known, but one hears less of the cathedral; yet it will probably, when complete, hold its own in point of design with either of these buildings and is far more interesting both from its nature and as a remarkable example of how to build a large church that cannot be completed in one generation. It has been usual to build one end, the chancel or little more—to put up, with contracted floor space, that is to say, and spend resources in completing it vertically. Bishop Doane has adopted the more satisfactory plan of enclosing his whole floor area and limiting his building in height. It sounds unpleasing, but is carried out so that there is no sense of loss in height. The stonework is complete up to the sill course of the triforium. The triforium wall will be double, consisting of an inner half of stone to show in the church, and an outer half of brick, which will be hidden in the aisle roof. This latter portion is built now and, by putting the temporary aisle roof below it instead of above it, the brick triforium wall is converted into a temporary clerestory of brick. From this the temporary roof of rough timber springs, as the vaulting will ultimately spring; and, as the lines of the roof follow very much the lines the vaulting will take, and the roof rises to the same height, the proportions of the interior are perfect now. This is the principal thing. The eye is satisfied with a sense of sufficient height, without desiring to penetrate the comparative gloom of the roof. At its natural level all is complete: carving stained glass, stone pulpit, wrought iron screen, choir stalls, altar and reredos. And, what is more important than these details, the plan is complete; so that the whole effect of aisle and ambulatory arcades with their pillars, (seven feet across the greatest diameter) is there. There can hardly be a nobler church in the country, although there is work yet to be done which is estimated at over $300,000.

The way in which the work has been done is also instructive. A church building is especially susceptible of division into parts and of estimation by parts. By subdivision of the work in this way every pillar, column, window' portal, and of course the furnishings and accessories, have been provided by separate hands, by gift or collection of the cost and many Albany families have in this way become provided with an enduring memorial, duly carved upon the stone as a portion of its decoration. A list of the remaining works hangs in the porch, with the estimated cost set opposite, so that anyone, who has money to give or to bequeath, can take his choice of works, ranging in cost from $1,500 for a buttress to $70,000 for the towers and spire

---

Boston is a beautiful city; there is no doubt about that. It always had beautiful suburbs and a beautiful nucleus, in the Common; now they have connected the suburbs with the Common by continuous drives; all of which is well known to the readers of this journal. But what struck us as an extra to our expectations was the extreme neatness of everything. This was an essential part of the city's beauty, and an aim in this direction has evidently got to go hand in hand with the aspirations, of which we usually hear most, in the direction of parks and squares and statues. New York is squalid beside Boston, because of its dirt. Fifth avenue was filthy. There may be extenuating circumstances in the near neighborhood of the excavations for the Fourth avenue subway; but whether regarded as temporary or permanent, the untidiness of the streets detracted very much from one's sense of pleasure in viewing the buildings. A city is very like a horse, it must be well groomed to look its best.

Another essential part of the beauty of Boston is the absence of vulgar bustle. Once upon a time there was a continuous procession of street cars along two sides of the Common. Now there is not a street car to be seen in that neighborhood; yet, by entering a small, unobtrusive building at the corner of the Common next to the business streets; and going down a flight of steps, one can take his choice of direction. Cars for all parts of the city, which have already discharged at another platform, draw up for passengers and depart continuously. In the streets above there is peace and quietness; and this is another important factor in the beauty of Boston. The "City Beautiful" cannot have tram cars moving through its streets.

Boston has an additional advantage in the way in which its districts are massed, so that business has one solid quarter to itself, and beauty, as represented by the best residences, another. And the outer fringe of the residence quarter is in touch with the park system, so that the rich suburban resident can drive all the way from home to within a block or so of his place of business without mingling with commercial traffic. It is partly on this account that one receives so unbroken an impression of Boston as a beautiful city. When we took a trip into the old town to see Christ church—one of those delusive investigations of historical scenes,

by which the picture of the imagination, true in conception however unlike in minor details, is forever dissipated by an intrusive recollection of the present scene, to which time has usually brought a change which is at variance with its former state. In the case of Salem street, Boston, along which Peter Faneuil and other distinguished colonials once went to church in silk truffles, the place now swarms with Jews, and the street seemed to be inches deep in a litter of paper. If such districts adjoined the beauty part in Boston as they do in many towns, so that one was conscious of their neighborhood, it could not but disturb the impression of elegance, which in Boston is unbroken. But it is only the English tourist who finds his way to the old town (though Christ church is well worth seeing). A person with an office near the Common, and a home in the Back Bay or the suburbs beyond, may live from one end of the year to the other, if he wishes, without contact with ugliness or uncleanness. If that is the end that is desired in the present agitation for beautiful cities, the general plan of Boston may be taken as an illustration of the truth that a city, like a house, if it is to be perfect, must have its working parts combined by themselves, and its living parts combined by themselves, as broadly as possible and in contact only where necessary.

It is remarkable how Richardson's pre-eminence has been challenged by the general advance in architecture. The solidity and excellence of workmanship, for which he was once so conspicuous, have now become ordinary, and his refinement, which was real, but in the large way—the refinement of "an oiled and curled Assyrian bull"—is surpassed, in the work of his descendants, by a refinement more in scale with modern life. In a great work like Trinity he still shows up in his greatness. It is a pity that the porch was not built at the same time as the church, when Richardson was young and developing his style, instead of when he was old (in growth if not in years) and his work was passing into the period, which comes to all original art, when development is at an end and degeneracy begins. The porch of Trinity is an offshoot, not of Richardson's growth but of his success, and more than anything in his own work resembles, though in a better way, the work of his imitators.

It is worth noting how the interior has been injured by the gloom into which it has been thrown by the use of Tiffany glass. The transmission of light appears to be a secondary consideration with the American stained glass worker. As long as the window is sufficiently translucent to show its color he seems to ask no more. The result in Trinity church is a loss greater than the gain of the windows which, from their unreligious character, is in any case doubtful.

One cannot conclude the notes of a tour in the big cities in the United States without some reference to the high development of the hotels. Bathrooms and fixed basins in connection with the bedrooms is an old story now, but still the greatest comfort. The latest invention appears to be directed to means of communication between the bedroems and the office. In one hotel we found on the wall a long list of possible requirements with a moveable pointer attached. Anybody or anything, from the manager to a glass of ice water, if one simply pointed at its name, forwith came knocking at the door. The simplest and best arrangement was a telephone in each room. One had only to "speak in an ordinary tone of voice" for what one wanted. The best of such an arrangement is the ease with which a party of travellers can communicate with one another. There is nothing to prevent an early morning explorer speaking from a telephone exchange a mile away to the rest of his party, in their bedrooms, about breakfast.

No invention will, however, make an American hotel comfortable until the one great invention has been made by which it will be made impossible for the heat to rise above a certain point. A procession of marble halls are of small comfort to the traveller as long as they are heated so that he is driven from his hotel to walk the street, a houseless wanderer.

W. A. Langton.

BY THE WAY.

I was pleased to observe the protests made in the Toronto press recently against the advertising signs which this year began to make their appearance in Muskoka. Among the offenders of good taste in this direction was a prominent Toronto jewelry firm. Every visitor to the Muskoka Lakes should join in this protest against the commercial enterprise which in the pursuit of gain would destroy the beauty of one of Nature's masterpieces. The violators should be made to feel that the placarding of this beauty spot is calculated to alienate rather than attract customers.

× × ×

The British architectural journals contain references to a series of tests of ventilating cowles by a committee of the Sanitary Institute. A singular feature in connection with these tests is the fact that they are said to be a continuation of tests made under the same authority twenty-five years ago. Why they were not completed when originally begun, and why so long a period was allowed to elapse before they were revived, are matters regarding which no explanation is given. It is also singular that even now the tests are criticized as being of little real value owing to wrong methods of procedure and the failure of the committee to include cowles and ventilators of modern design.

× × +

Old London Bridge, around which so many historical incidents and associations linger, is to be widened by 12 feet, to accommodate the ever-growing traffic. Statistics show that more than 100,000 persons and 22,000 vehicles pass over this bridge each day. It is proposed to devote 9 feet of the extra width to the use of foot passengers. The bridge rests on the wooden piles of an older bridge, and soon after it was reared, in the 'thirties of last century, the foundations made an unequal settlement. The defect was put right, and the present architects are confident that the new burden can be safely added. The alteration is expected to occupy three years and to cost £100,000.

× × ×

In company with an architect I was examining and admiring a photograph the other day. My companion remarked that the excellent shading in the picture was largely due to the use of white paint on parts of the building. Out of this arose a conversation on the sudden revival of white paint for exteriors. This revival came as a natural accompaniment of the return to favor of the Colonial style in architecture. Its appropriateness to buildings designed in this particular style, is as clearly apparent as is its misapplication to buildings of every class. The man who paints white his gothic fronted house on the strength of the pleasing impression made upon him by the effect of white paint on the broad overhanging eaves of his neighbor's residence, will suffer a severe disappointment. Like many other good things white paint is "all right" when put in the right place, but is "all wrong" when placed otherwise. Just here comes in the difference between the trained and the untrained architect or painter—the one knows with certainty what materials and methods will secure a pleasing and satisfactory result, the other guesses at it, and misses more often than hits the mark at which he has aimed.

× × ×

Mr. Harry Hems, the well known sculptor, of Exeter, who was in South Africa last year, contributes to the British Architect some impressions of the building materials and methods in use in that country. Under this head he says :—"The bricks at Cape Town were the most rotten things I ever saw in my life, and the building, for that matter, more particularly outside the actual capital, is precisely as bad. Buildings appear to be carried up rough, cheap, and very nasty, the wretched bricks being laid in clay mortar, and then their faces slobbered over with plaster. Foundations are built of stone rubble; also with so-called mortar, which is, pure and simply, clay. Stores and large business places are carried up with the same horrible bricks just as roughly as humbler edifices, the walls afterwards being covered over with red plaster, and then pointed down to imitate proper brickwork—all artificial and a sham! There appears to be no recognised Building Act or by-laws. The municipal authorities have a few simple regulations and rules, but they are practically totally ignored. Fiar clay, I am told, is to be found on the Cape Flats and the kaolin in the Cape district, but I confess to never having seen it. On the other hand, in Natal—'the Garden Colony'——splendid red bricks are to be seen in many parts. At Pietermarizburg I was much struck with the excellence of the bricks and the capital manner in which they appear, almost invariably, to be laid. At Mafeking, in Bechuanaland, I found the bricks mostly in use to be simply sun-dried—made of a mixture much like Devonshire "cob"—and each measuring about two feet by one foot by one foot. The Post Office, for instance, at that gallant little place is built of these big unburnt bricks. As one gets farther north the cost of building materials naturally increases. At Bulawayo, at the time I refer to, fair bricks could be procured for 70s. a thousand; whilst at Gwelo, rather more than 100 miles further on towards Salisbury, the same kind of brick cost £6 a thousand."

+ + +

Scientists connected with the Dominion Department of Agriculture have been working upon what promises to be a very interesting discovery, namely, that all objects in nature are covered with a very thin coating of liquid air. It appears, according to this idea, that the walls of houses, the furniture of rooms and the ground over which persons walk are all spread over with a thin film of air in this highly concentrated state. The basis of this theory is the fact that any solid has the property of condensing upon its surface gases or the vapors of liquids, such as the water vapor of the atmosphere. If the wall of the room is touched with the finger it encounters, not the wall itself, but a film of gas that covers it. This film is not composed of one gas however, but of several, the molecules of which have adhered to the surface of the wall. In addition to the water vapor there are oxygen, nitrogen and carbonic acid gases. Taking them all together they go to make up something which would probably, if one could analyze it, be indistinguishable from liquid air. These gases, together with more or less water vapor, say the scientists compose the air of the room. The molecules are darting about in every direction, and as they come in contact with the wall some of them adhere to it. Countless numbers of them together, it is held, form the thin film described. To get rid of the thin film of liquid air, it is stated, one may employ heat, and by raising the temperature of the wall the coating of gas may be thinned gradually until it is entirely driven off.

THE NECESSITY OF CARE IN EXCAVATING.

The importance of careful work in excavating and reinforcing old foundations and preventing all chance of undermining them when disturbed is demonstrated, says the Engineering Record, by a recent accident to a building on East Thirty-fifth Street, New York. A new cellar was being carried down about 10 feet below the rubble foundations of the brick side wall of a four-storey brown stone front residence. The excavation was made up to a vertical plane in the face of the existing wall through very soft rotten stone which could be crumbled in the fingers. No sheeting or underpinning was attempted, and no support was given to the building except by some horizontal cross-braces between its side wall and the adjacent building on the next lot, reaching across the excavation, and some of them bearing against the middle of the wall between floors. The side of the excavation caved in, leaving a sloping bank with a steep angle running back several feet into the basement of the house and carrying out about 20 feet of the footing and a section of the wall above, about 10 feet high in the middle. Fortunately the wall was of such good construction that the bricks arched and carried the upper part over the opening without causing the collapse of the whole building. Pairs of long steel I-beams were immediately set as needle-beams to carry the wall above the break, and were supported on vertical wedged shores from the bottom of the excavation and on jackscrews set on longitudinal sills on the basement floor 10 feet or more back from the wall so as to be beyond the crumbling edge of the bank. The wall was thus held until underpinned.

TORONTO ENGINEERS' CLUB.

The Club has resumed its weekly luncheons and has changed the day from Saturday to Monday. At the regular meeting on December 5th a discussion will be held on "Wireless Telegraphy" introduced by Mr. T. R. Rosebrugh, of the School of Practical Science. At the meeting on the 19th of December, Mr. W. H. Tatton, Chief of the Railway Signal Service, will give a paper on "Interlocking Railway Signals."

ONTARIO ASSOCIATION OF ARCHITECTS.

A water color class has been organized under the direction of Mr. C. M. Manly, the well known water color artist. The class will meet in the Association rooms every Saturday afternoon at 2 o'clock. Quite a number of persons have already joined. The first meeting was held on the 23rd inst.

The weekly luncheons in the Association rooms every Tuesday have been successfully continuod throughout the summer, and since the close of the vacation season, the attendance has steadily increased.

PRESERVATION OF STEEL STRUCTURES.*

BY W. CHAMBERS, C.E.

In speaking of engineering structures our thoughts naturally turn to those Titanic erections spanning the rivers and estuaries round our coasts, supporting a flying freight of human life and valuable merchandise, of which the most notable example is the great Forth Bridge; and we have to bear in mind that in every steel structure, be it of lesser or greater magnitude, corrosive forces are at work to weaken and even to endanger its stability, and it may truly be said of steel that as the "force of gravity never sleeps" so "corrosion never ceases." It behoves us then to see that proper measures are adopted to counteract this evil.

The object in applying paint is twofold; first to protect, and incidentally beautify. The medium in general use, namely, white lead, in its pure state contains 70 per cent. carbonate of lead and 30 per cent. hydrate of lead, and is manufactured by subjecting metallic lead to the corrosive influence of vinegar and the fermentation of tan bark. Being frequently adulterated with carbonate and sulphate of lime, it can be tested in a simple manner by placing some of the powder on a piece of charcoal, when by applying a flame from an ordinary blowpipe, it is, if pure, soon reduced to a metallic mass; if adulterated, however it forms a black cinder-like substance, and even small quantities of an adulterant can be detected in this manner.

White lead is not a very stable body, and, when exposed to sulphurous fumes, is changed from a carbonate to sulphide of lead; and it has been proved by long experience that when mixed with oxide of zinc, it has increased durability, improved spreading power, easier working qualities, and greater permanency.

Red lead is obtained by calcining and oxidising white lead. It is of considerable specific gravity, and forms the basis of a durable paint. To test its purity it should be dissolved in dilute nitric acid, when any deleterious matter will remain as a sediment.

Ferric oxide does not take a high rank as a protective agent, although its cheapness and good colour give it an intrinsic value. One authority on oxide of iron as a pigment for coating metal says it is actually dangerous for that purpose, as it only combines with oil in a mechanical way, and is adversely affected by the sulphurous fumes from locomotive smoke. To test ferric oxide paint, a small quantity should be heated and ignited to burn off volatile matter; if the residue is placed in hydrochloric acid the ferric oxide is dissolved, leaving any solid matter as showing the extent of adulteration.

As already stated, the object in providing a covering for metal is to exclude moisture and to protect it from the atmosphere, which is always damp.

Linseed oil is a component part of ordinary paint, but cannot be used without a pigment, as when drying it becomes very porous, and under the microscope resembles the honeycomb appearance of a piece of tripe.

Raw linseed oil contains 5 to 8 per cent. water, also impurities called "mucosities," composed of vegetable albumen and mucilage, which prevent drying. The raw oil requires 5 to 6 times as long to dry as does the same oil after it has been boiled. The heat then evaporates the water, and throws down the impurities that would otherwise decay and generate acids that would attack the oil in the paint. The changes that occur when boiling linseed oil are complicated, and have not been clearly defined by chemists. We know, however, that during the boiling process, by the addition of sulphate of zinc, muscosities are thrown down to a notable amount; also that the counteracting effects of other oxidisable substances, such as umber, litharge, oxide of lead, and peroxide of manganese, when added, increase the oxygen-absorbing power of the oil. The addition of about 1 per cent. of the above elements, and injecting a current of air when boiling, evaporates the water, precipitates impurities, and evolves fumes that otherwise would become injurious to metal surfaces. Where paint is used as a protective medium several coats have to be applied, each to fill up the porosity of the previous coat.

The necessity of only employing pure pigments is manifest, as thousands of tons of deletrious matter are annually sold, such as burnt ore containing an appreciable percentage of copper salts and free sulphuric acid, such as is obtained from burning iron pyrites. To counteract their acid tendencies chalk is added, also Spanish white—which is another chalk preparation—and Spanish brown, an earthy substance, principally clay.

Other materials of a harder nature, such as silica, graphite, barytes, ground slate, brick-dust and kindred substances do not combine with the oil, and form only a mechanical mixture with it, and after its binding effect has become dissipated by atmospheric influence, nothing but dust remains, which is readily dispersed, leaving the metal wholly unprotected.

So much depends upon the proper application of any protective coating that an ill-important element is to have the surfaces, in the first instance, clean and free from rust. Where rust spots are deep seated, heat from a painter's torch should be applied, when in a few seconds the rust is converted by the heat into peroxide of iron, and can be readily dusted off. No coating of any kind will properly adhere to greasy, rusty, or dirty surfaces. These should be either burnt, to remove old or blotchy paint, or scraped and washed with soda lye to remove grease or dirt, and all mill scale carefully removed.

After repeated examination of several materials, I have ultimately found a coating that answers all modern requirements. It is dense, i.e., non-porous, elastic and durable; not affected by extreme heat, is easily applied, and presents a good, even and smooth finish. Its covering power is considerable, 1 gal. being sufficient to cover 1,000 square feet. It is known as "Carbonising Coating," and has powerful adhesive qualities that ensure absolute protection to the metal. It is unaffected by sulphur fumes, acids, and ammonia, successfully withstands high temperatures, and cannot be readily removed by abrasion.

As an indication of durability, it is being adopted by the Indian Government for the preservation of buildings exposed to the heat and damp of tropical climates. This material should prove invaluable for preserving intact such steel structures as may be carefully coated with it; also for maintaining intact the scantling of the beams and girders now largely incorporated into building construction, and so secure their durability and stability by ensuring them against rust and decay.

The great Forth Bridge has an exposed area of 145 acres, requiring 100 tons of paint to afford only one coat. When completed, three different kinds of paint were tried—one on each cantilever; and as an indication of their shortcomings as protective coatings, it is stated that 90 men are permanently engaged in scraping and painting the immense structure, and that the work cannot be done with fewer hands, thus indicating in a striking manner that the selection of a suitable protective medium is not the trivial detail that many suppose it to be.

*Abstract of a Paper read before the Belfast Engineering Association.

ARCHITECTS AND ENGINEERS IN BUILDING CONSTRUCTION.

The extent to which engineering in one branch or another has entered modern building construction is scarcely realized until one considers in detail a great modern office or other building, with its heating, lighting, ventilating and elevator machinery and the motive power required to operate it. The same observation is applicable even with greater force to a considerable class of buildings in which the development, transmission and application of power are elements of materially greater relative importance. This complicated combination of purely structural work and machinery installation has inevitably raised important questions both as to the amount of fees for the design and supervision of the entire work and the division of them between the architect and engineer. These questions are comparatively new, as it is but a few years since the design of a building involved so little outside of strictly architectural work that nothing beyond the services of the architect were needed, although in the older practice of the architect his field was considered a rather broad one. Indeed, nearly two thousand years ago Vitruvius wrote: "An architect should be ingenious and apt in the acquisition of knowledge. . . . He should be a good writer, a skilful draughtsman, versed in geometry and optics, expert at figures, acquainted with history, informed in the principles of natural and moral philosophy, somewhat of a musician, not ignorant of the sciences both of law and physic, nor of the motions, laws, and relations to each other of the heavenly bodies." And then, as if to confirm or justify the professional character of the architect, and possibly to indicate the propriety of joining the expert services of other professional men to his own, he further wrote: "Moral philosophy will teach the architect to be above meanness in his dealings and to avoid arrogance . . . and, what is of the highest importance, it will prevent avarice gaining an ascendancy over him: for he should not be occupied with the thoughts of filling his coffers, nor with the desire of grasping everything in the shape of gain, but, by the gravity of his manners, and a good character, should be careful to preserve his dignity."

The overlapping of the professional work of architects and engineers has already received serious consideration, and a committee report touching the matter, printed in the Engineering Record of December 22, 1900, was made to the last annual convention of the American Institute of Architects held in Washington, D.C. The committee made its report after a conference with a committee of the American Society of Heating and Ventilating Engineers, with many engineers of various specialties and with architects representing all sections of the country. The committee recommended in substance that the Institute's schedule charges be so amended that the minimum fee of the architect for those portions of his work involving electrical, mechanical and sanitary engineering, heating and ventilation, be made 10 per cent. of the cost of the corresponding parts of the work; that the architect select engineering experts and that the latter render their services under the supervision of the architect. On the whole, the terms of the report of the committee, when reasonably interpreted, may be considered satisfactory, and yet there would appear to be something further to be said. The Institute has not devoted serious attention to this matter any too soon, and it probably would be wise for the American Society of Civil Engineers, or for other engineering bodies, to devote to the same subject equally serious consideration. In this region of professional work architects and engineers ought to co-operate both cordially and comprehensively. Both professions are deeply concerned and the most satisfactory results can only be obtained by mutual effort. As a matter of fact, general principles of co-operation could be at least outlined which would be of material benefit in other work than building construction. It is well enough that the architect should be the responsible head in the design and construction of buildings, but it would be equally suitable and essential that if an architect co-operated with an engineer in the design and construction of a bridge, the engineer should be the responsible head. Again, it is in the highest degree essential that in work where engineers and architects co-operate both should act from the initiation of the design work. This may not be essential from all points of view, but it certainly is essential from the point of view of estimated cost, and that is a point of view which does not always receive sufficient consideration. A client has a right to know what the cost of the work will be within a narrow margin, whereas the estimated costs of buildings with the plant involved are often grossly in error. Such a result will almost certainly occur if the services of the auxiliary expert do not begin with the inception of the design. His preliminary work ought to be performed coincidently with that of the professional principal, in order that all the elements of cost may be developed suitably to the purposes of the complete design, and, so far as their principal features are concerned, in final shape.

The report of the committee of the American Institute seems to bear entirely on the matter of machinery plants or parts of the work other than those of a structural character. As a matter of fact, there may frequently arise structural questions requiring auxiliary expert services. In most cases such expert service would be rendered in connection with the design of steel-work or foundations. Obviously these features should receive the same treatment as the others of the same class—that is, those beyond the limits of a purely architectural character. Apparently it was the opinion of the committee that all such structural matters, should, so far as the fees are concerned, be considered architectural only. It may reasonably be doubted whether that is the proper conclusion. Certainly some foundation work and occasionally special structural design may properly be classed in the same category as the special lines of installation named by the committee and covered by the 10 per cent. fee. It is full time that these and possibly other fields of professional co-operation should be carefully considered by both engineers and architects, to the end that they may in actual practice be suitably recognized and that an adequate distribution of responsibility and fees may be reached. —Engineering Record.

According to the Irish Builder, the Irish oak of which the famous roof of Westminster Hall is constructed was grown in Dublin, in the vicinity of where now stands Christ's Hospital, or Blue Coat School. Centuries ago there stood here a famous oak forest. Some people say the Westminster Hall oak came from the county of Carlow, which, up to the present century, was noted for its fine oaks. In the middle ages Ireland was a great oak-growing country.

UNSAFE PROJECTIONS.

The city coroner of Manchester, England, recently called attention to the necessity for more frequent and careful inspection of balconies and other projecting features of buildings. His remarks on the subject were the outcome of an inquiry into the death of a young woman who was killed by the fall of a large stone from a balcony. Shortly before the accident the balcony had been occupied by three ladies for the purpose of viewing a procession. Examination showed that apparently there was nothing to hold the stone in position, and the wonder was that it had remained in place for a quarter of a century.

The coroner said owners of property frequently neglected to see whether balconies and other such places were in a safe or unsafe condition. They seemed to think that they would last forever, and it did not occur to them that material would wear out. The accident, he said, showed how necessary it was that buildings should be regularly inspected. If the accident had happened within a short time of the stone having been fixed in position, he would not have hesitated to have advised the jury to send the responsible person for trial on a charge of manslaughter. In this case, however, the stone had been in position for more than twenty-five years. At the same time, he added, a person ought not to be allowed to come into a court and say: "I did not know that it was dangerous." If they had examined it they would have found it out. He only wished that the law was strong enough to allow him to send some one for trial. If the jury were satisfied that it was an accident, he would take their verdict to that effect.

The building inspection in most of our cities is much less thorough than it ought to be, due in a measure to an insufficient number of inspectors, and it is extremely doubtful whether the safety of the projecting features, pediments, etc., receives any attention whatever. Yet pedestrians should as far as possible be protected from injury from this quarter.

STEEL VS. CAST-IRON STANCHIONS.

Fashion has some influence in the building trades, and brings with it a certain amount of practical imbecility says the Builders' Reporter. It is now the fashion with some architects to specify rolled steel as the material with which to build up columns and stanchions. Under some conditions this is suitable for large and very heavy structures, but for ordinary buildings it will not bear comparison with cast-iron. In the first place the strength is to be considered. The calculated ultimate strength of an English steel 9 inch by 7 inch rolled joist 7 feet high is 22·4 tons per sectional square inch, and that of a cast-iron column 7 inches in diameter is 26·5 tons per sectional square inch, which indicates that for equal carrying capacities the steel stanchion must have 18 per cent. more horizontal sectional area than the cast-iron column, and taking into consideration the difference in specific gravity the steel stanchion will be 27 per cent. heavier than the cast-iron column. It will be noticed that the same ratio of width to height has been kept in both materials. When stanchions are made of various sections rivetted together, we cannot be certain that the rivetting is sufficiently uniform to insure each part receiving its due share of the load, so that probably the strength will be less than that given above for an element in one piece; the cost per ton is from 30 to 40 per cent. more than cast-iron, so putting all things together in the most favourable form for built-up steel stanchions the cost will exceed that of cast-iron columns by about 65 per cent. This is a considerable amount for a client to pay for the ignorance of his adviser. The attachments to small built-up stanchions—brackets to take girder ends—are awkward, as the whole stress must be picked up by rivets, often in an insufficient space, whereas in the cast-iron column or stanchion there is continuous solidity throughout the work, and whatever shearing sectional area is required can be secured in a comparatively small space.

IDEALS IN ARCHITECTURE.

As we have more than once remarked, there is a growing desire on the part of those who have some authority to point the way, to plead for higher ideals in the matter of latter-day architecture. One of the most recent voices from what may be termed the "professional pulpit," is that of Mr. G. F. Bodley, A.R.A., F.S.A., who discourses in the March number of the National Review, and seeks to lay down certain principles or characteristics of good architecture. One principle is, with rare exceptions, he declares, eminently absent in modern work—the expression of a real artistic refinement. "Refinement, alike of general design and of detail, is sadly lacking in modern buildings. There is an indescribable charm, a poetry, and a sense of repose about ancient architecture that one seldom sees in later work. It is not only that the mellowing hand of Time has mysteriously wrought the effect, it is the reasonable, manly sentiment that prevades the whole animus of old architectural buildings. If I may so speak, the expression is one of greater courtesy, combined with less display and greater nicety of sentiment, than, alas, so much of our modern buildings can show. The same may be said of other works of art. The tender touch, the grace, the quiet power—how rarely we find them in modern literature or art. Certainly the voice that speaks so powerfully or so pleasantly in ancient architecture discourses in less courteous tones, or but feebly, from our modern buildings."

In the building of the present day, he goes on to declare, there is too little that we can call architecture. "Where, in our works, I would ask, are the architectural influences that would tend to educate the people? Look at any of our new towns where there is not the presence of old buildings to redeem the general aspect of ugliness and vulgarity. It is not that the houses are merely destitute of ornament; there is the presence of vulgar and ugly so-called ornament in plenty, sometimes, indeed, in heavy and tiresome profusion. The shape and proportion of the houses seem to have come by chance, and without design. The ugliest materials have been used—bricks of the poorest color, and of ungainly size, the roofs covered with cold-looking blue slates of too large dimensions, and the details of the exterior are in every respect without interest or refinement. Inside we find the same poverty or vulgarity of design everywhere. The meanness of stained deal seems to have been delighted in, or, if it could be afforded, that ugliest of all woods, "pitch pine," with its coarse grain and hot color. Color and form alike are without beauty. I am not thinking so much of those unhappy new towns amongst us which are devoted—I had almost said doomed—to manufactures and industrial works, where the sky is darkened, Nature disfigured, and the enjoyment of any art almost impossible. I am thinking rather of modern watering-places and the like—places devoted to leisure and pleasure, chosen for their brightness of climate and beauty of scenery, but presently made hideous by a very nightmare of badly designed and worse constructed buildings. In the new towns of which I speak the inhabitants live surrounded by these buildings, to the great detriment of all artistic perception. Or, look again at our London houses of a slightly older and better period. Our "long, unlovely streets" are without interest or dignity, and, with rare exceptions, a uniform dullness at best prevails. You may pass through many miles of our London streets without seeing one redeeming building, or even a part of any such building. There is a uniformity of dreary ugliness alike in Camden Town and in Belgravia. Whitechapel is better, for there are some old buildings there. Is not all this a satire on our civilization and on our culture?"

Coming to some of the principles and characteristics of architectural design, he enumerates Refinement, Concentration, True Use of Detail, Symmetry, Economy of Material, Contrast, Avoidance of Extravagance of Manner, Suitability, Harmony, Color, Work founded on that of the past, Consonance with Nature; lastly, Truth. Dealing with them in turn, Mr. Bodley affirms that refinement of design is the chief principle lacking in the present day. "What is the history of architectural art in our own land? What is the one principle that led on from century to century, from style to style, but the desire for refinement? Nature is our great guide, although we are unable to gauge her redundance of life, its variety and infinite delicacy. Now it is in the refinement of architectural work whereby this expression of life is chiefly shown. According to the material and means at command, there should be the careful exercise of artistic power if we are to bring out to the utmost the expression of life. This is a great principle of all art, and one to which limits can hardly be assigned. It should animate every detail of our architectural work; the carving of natural ornament, however conventionalized, architectural mouldings, and the like, should all express the highest gift of Nature—LIFE. We see it in all good architectural work, in the branching vault and the graceful column from which it springs; in the steady, sturdy, but thrusting buttress; in the varied modelling of carved ornament—yes, even in the mouldings of a cornice or of a string course. Whatever in architectural work is endowed with the expression of death is bad art." Good art, on the contrary, is ever imbued with the expression of life, and it is, he adds, refinement of design that mostly helps to give this expression. Nor is it contrary to principle that much of the best architectural ornament is conventional, for conventional ornament should ever be imbued with the spirit of Nature—with its energy, its repose, its beauty of detail and its breadth of effect.

Concentration of Ornament, especially for our larger buildings, is his next point, and one which he asserts is too much neglected in modern architectural works. "The eye wearies of and the mind fails to be interested with a monotony of richness. It is an unwritten law that buildings should be designed in good proportions, that is, with the proportion that has an expression. Another unwritten law or principle with which he deals is that of the true use of detail. Mr. Bodley holds it to be a great but manifest error to suppose that by boldness of detail a building is made to look large. The reverse is invariably he case. Not that it is only detail carefully used which gives scale to a building. The multiplication of parts is an arrangement of much use for this purpose. We know, he says, how skillfully this was done in Mediæval and Renaissance buildings, and the study of the best designed ancient works will make the intention very apparent. Compare, for example, Milan Cathedral with Westminster Abbey, or York Minster, or with other great Gothic churches.

Symmetry, "for the most part applicable to and of chief use for large buildings and those of monumental character," is next touched upon, and then Economy of Material, which is, again, another law of refinement. "Engineers make their calculations of less and more and tell us this or that 'will stand.' But good architecture is not only 'built to stand'; it is built to last from generation to generation. It is no waste to build in such a manner that the eye and the mind are satisfied. Centuries hence men may behold the buildings as we see them now, if not cruelly dealt with by the more ruthless hand of man—the gentle, slow, natural decay of time will leave the inheritance well-nigh untouched. Such strength, combined with a nice economy, should be the aim in designing buildings."

Contrast—"In all the best architecture you will find a noble simplicity of design, due breadth of surface, contrasted with delicate detail"—is followed by Avoidance of Extravagance of Manner. "One has seen too much of this of late in Gothic work. A shaft, only two or three times its diameter in height, is surmounted by a capital out of all proportion to that shaft. This ugly affectation is an exaggeration that becomes a caricature. There is one kind of strongly marked proportion, however, that we need hardly fear to carry out in these days. I mean that of considerable height. The controlling exigencies of economy too often prevent our churches, for example, from rising into stately and inspiring proportions." As to Suitability, "we need not go abroad to find a style in which to design buildings in England. Let us keep the genius loci. Both in Gothic and in Renaissance buildings among us there has been too much copying of a foreign manner, unwisely imported from the Continent. Our own English architecture is second to none for beauty and poetry of design. If on the Continent the architecture is more grandiose, yet it often lacks the refinement and the poetry of sentiment of our English work." Touching on Harmony, he tells us that no eclectic school which mingles styles incongruously will ever be long-lived or successful. The result, if not one of continuous discord, affords but occasional harmony.

Colour is another and an important part of architectural work, whether in the use of marble or other constructional colour, or in painting, and Mr. Bodley also speaks of Consonance with Nature. "Architecture, like music, is not an imitative one, yet its characteristics should be those of Nature, in the spirit though not in the letter. It is the strength and the delicacy, the refinement and the richness, and the other great attributes of Nature, which we should endeavor to embody in our works, rather than any exact imitation."

Finally we come to Truth, the one great unwritten law of architecture and all art. "I need not dwell on this part of our subject; nevertheless, what are many of

our new street fronts in the city and other buildings elsewhere rising around us but examples of most untruthful architecture? Iron columns and iron girders are concealed by stone columns and thin stone friezes and the like deceptions. It is an unpleasant and, indeed, a wretched style of building, without truth or dignity. Should a fire try the nature of the work; the writhing columns and the bending girders will soon show that they are found wanting in that first necessity of good building—stability—and the disguise will be manifest. To conclude, let me say that architecture and all art should be animated by some great and leading principle. Religion is the highest. The noblest buildings in the world have ever been those consecrated to her service. We see this alike in the Pagan temple and in the great churches of Christendom." How far any revival of a great school of architecture is, he adds, possible is a question. The want of unity of feeling, as compared with other times, is one serious impediment to the formation of any school of Art. Is any such unity possible? Is any such school of architecture possible without unity? No doubt the work of architects in these days is, he admits, one of difficulty. It is an age of science, not of art; architectural tradition has been cut off, or rather, alas, we inherit a century or more of bad tradition.

There are, Mr. Bodley says, some signs of the dawn of better things amidst the general gloom, and we may hope, he remarks, that a more intelligent interest may yet be taken in architecture. "Time was when she was the Queen and mistress of all the arts. Is it not for our unfaithfulness that she has abdicated her throne?"

FRESCO PAINTING IN ITALY.

Dr. G. C. Williamson recently gave an interesting lecture on "The Art of Fresco Painting in Italy," in the fine old hall of the Painters' Company in London. The lecture was given for the benefit of the incorporated Institute of British Decorators, and there was a good audience, who followed with close attention Dr. Williamson's sketch of the development of fresco painting, and greatly enjoyed the beautiful series of pictures which were thrown upon the screen to illustrate the sketch.

The lecture began by describing the difference between true fresco, which meant painting on the wet clay as it was laid down, and fresco secco, i.e. painting in tempera on a dry surface, the medium used for tempera being some gelatinous substance such as white of egg or size. In England, he said, there were no examples of the fresco, though there were walls still to be seen which had been decorated in a mixture of the two styles—the background painted wet, the detail added when the clay had dried. This was the method that was also followed largely in Italy, though there, of course, were to be found plenty of examples of fresco buono, the real thing.

Dr. Williamson's examples began with Cimabue, whose famous Florentine Madonna was shown. Giotto came next; several of the scenes painted in the Lower Church at Assisi, one from the arena Chapel at Padua, and others at Florence were offered as characteristic specimens of different periods of his career. A number of lovely paintings with which Fra Angelico adorned what is now the Museo di San Marco, represented his wonderful art very satisfactorily, and Fillippino Lippi was also well represented on the screen. He it was, the lecturer said, who began to make his paintings rather pictures than scenes. Benozzo Gozzoli carried this a step further. He, too, began the practice of introducing into sacred subject-pictures portraits of his contemporaries, a practice that Ghirlandaio carried further still.

With the full tide of the Renaissance came the change from the simple piety of the earlier painters to the enjoyment of beautiful things for their own sake, and soon enough painters were painting pictures to glorify individuals instead of to glorify God. The classic or humanist influence had a great effect upon Mantegna's work, and in it was seen also the desire for movement, which Luca Signorelli carried so far. In the work of Perugino and the Umbrian school was felt for the first time the sense of great space in painting; and when the time of Pinturiccio was reached art had become more and more pictorial and illuminated, and less and less episodic and devotional.

After this Dr. Williamson passed on to the great names of Leonardo, Raphael, Michael Angelo, and the Venetians, and so brought his lecture to a close.

NOTES.

Messrs. Band, Rolph & Meredith, architects, have opened an office at Sydney, C.B.

Mr. Hall Caine, the well-known novelist, author of "The Christian," "The Manxman," etc., like many other well-known men, began life as an architect.

Architects who may desire to exhibit drawings, models or photographs at the St. Louis Exposition of 1903 are invited to submit to the Directors separate lists for each class of exhibits before July 1st, 1902.

Messrs. McKim, Mead & White, Messrs. Carrere & Hastings and Messrs. Babb, Cook & Willard have been retained by the trustees of the New York Public Library to design and supervise the construction of the forty-two branch Carnegie libraries in that city, with the exception of one which it is expected will be constructed from designs furnished by Mr. James Brown Lord. The three firms above named, says the Engineering Record, are to act in collaboration and decide jointly all matters of common import regarding the designs and construction and other details relating to the various buildings. The designing of each separate building, however, and the supervision of its construction are to be entrusted by allotment to the several firms.

In the enrichment of the earlier Roman work, Greek taste prevailed until about the time of Alexander. From this period elaboration and abundance of ornament supplanted the more refined style of art. Carving of surface, as in friezes and mouldings, became universal. Foliage was made intricate in outline, and its surface-carving was so exaggerated that, although extreme fullness and richness were thereby gained, it was invariably at the sacrifice of simplicity and beauty of form. Scrolls grew out of each other, as in the Greek, but the foliated sheaths became long and formed into a number of divisions and subdivisions, often ending in an elaborate centre-flower. The sharp and crisp forms of the Greek foliage became lost in the imitation of obtusely-pointed or round-lobed leaves.

Professor Warren, an eminent Bostonian, speaking of latter-day architecture in New York, says: "In New York the influence of the Ecole des Beaux-Arts is paramount in much of the work, often even to the sacrifice, if not of local, of national character, so that many buildings look as if they had strayed from the Boulevards of Paris. Though we may regret this wholesale importation, this direct imitation, with all its mannerisms, of a style which is full of bad taste and solecism, in spite of the strength in plan and mass of its originators, it does not seem to express New York, and it certainly has been acclaimed there, and is affecting nearly all the work, while it has received but little welcome in other parts of the country, so that this direct Parisian influence has come to be peculiarly characteristic of New York, and may possibly be the starting point of a local manner of building. Lavish display, richness of effect, characterize most of the work, and express the luxury loving New Yorker."

PROCESS OF MANUFACTURE OF STAINED GLASS WINDOWS.

A stained glass window is more properly described says a writer in The Architects' Magazine, as one of coloured glass, for it is on such a glass that the artist paints—in monochrome it is true—his design, and the staining of the glass, if resorted to at all, plays but a very insignificant part in the decorative scheme. Perhaps one may be excused for describing the leading as the most important part of a stained glass window, for the very good reason that without the leading it would be necessary to paint a window in one piece. It is the lead which renders it possible to make up a composition of any number of pieces of coloured glass, and thus gives the artist an almost unlimited range.

In tracing a stained glass window from its inception it should be stated that the artist first makes a small colour sketch to scale, and from this he produces a cartoon in black and white of the exact size of the window space to be filled. The cartoon is now given to the workman, who produces what is called a "cut line" on tracing cloth; that is, he makes a tracing of the principal lines of the artist's picture, showing how the glass is to be cut to meet the needs of the colour scheme. Next is the turn of the master glass-cutter, who, in association with the artist, chooses the glass to be used in reproducing his picture, and when the choice has been made the glazier's skill is brought to bear in cutting the glass according to the indications given by the tracing. The glazier having completed his work, the pieces are put together in form on a sheet of plate glass placed over the cut line or tracing. Any portion of the coloured glass which has showing through it a principal part of the design, such as a head, a hand, or a piece of drapery, has traced on it so much of the artist's work in the pigment—brown being the colour, made up of black, red and umber. The pieces of glass are so placed as to show between them the black lines of the tracing—the outlines of the figures, &c., and every part where different colours are to be arranged in juxtaposition—and it is where the black lines are revealed that the lead subsequently assumes its appointed position.

Thus disposed in perfect scheme so far as colour is concerned, the "stained glass" is waxed into position on the slab of plate glass and then lifted on to an easel, where the task of painting is completed with all the care the artist can bestow on his work. It should be borne in mind that the painting is carried out solely in the monochrome already mentioned, and that it is the coloured glass showing through the brown pigment which produces such wonderful and, of course, almost imperishable effects. It has been mentioned that coloured and not stained glass is the correct term to apply to the principal medium of "stained glass" windows, and here it may be said that practically the only staining resorted to is in the production of gold colour. This is rendered possible by silver staining on white glass, a pretty effect very common nowadays in house decoration. It is really opalescent, but against the light a fine golden colour is shown. When the artist has finished his painting on the easel the pieces of glass are again separated and are fired in a kiln, being placed therein on iron trays. Heat having done its part in burning the pigment picture on to the glass the whole thing is waxed up again and retouching is resorted to, if necessary, with, of course, in that event, refining. Finally comes the glazing with what are termed culms of lead—long strips, grooved on both sides, to carry the glass. All the joins are soldered, and when the window is placed in position, iron bars from three-quarters to an inch in thickness are forced on to the mullion to support the picture, wire being soldered on to the lead, which holds all the portions of the colour scheme in position, and bound round the transversing iron.

CORRESPONDENCE.

CANADA FIRST (?)

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—During the last year or two a number of new bank buildings have been erected in Toronto at considerable cost. In these buildings the most expensive kind of materials have been employed, including a large quantity of wrought iron grilles, etc. Probably not less than $25,000 worth of this last mentioned material has been purchased, and so far as I know scarcely any of it was made in Canada, the material having all been imported from the United States. As one of the manufacturers in this line, I have never been asked to submit a tender for this material, although I have successfully filled orders for prominent Canadian architects in Montreal and other cities outside of Toronto. It would be a satisfaction to learn on what ground so much money has been paid to foreign manufacturers by Canadian architects. Is it because satisfactory material cannot be obtained from Canadian manufacturers, or is the price of the imported material less than that of the Canadian made article? As a Canadian manufacturer I do not expect to be given any preference, but think I am entitled to be asked to tender for this kind of material on equal terms with the foreign manufacturer. Canadian architects rightly object to commissions for important Canadian buildings being given to foreign architects. To be consistent they should, as far as possible, employ Canadian materials, and thus assist in the development of home industries.

Yours truly,

MANUFACTURER.

PUBLICATIONS.

LINEAR DRAWING AND LETTERING (for Beginners.)—By J. C. L. Fish, Asso. M. Am. Soc. C. E., Associate Professor of Civil Engineering in the Leland Stanford Junior University. Published by the author. Palo Alto, California. 7 x 10½, oblong. v + 65 pp. 46 figures. Limp cloth, $1.00 post-paid.

The opening chapter of the book gives instruction regarding the proper care and use of instruments. This is followed by courses in linear drawing and lettering and an introductory chapter on drafting.

"Blank Book for Lettering," by the same author, is designed to be used with "Linear Drawing and Lettering." Price, 25c.

Messrs. Houghton, Miffiin & Co., of Boston and New York, have just published a new book on "Applied Perspective for Architects and Painters," by Wm. P. P. Longfellow. Following an interesting introduction on perspective in Nature, are a series of problems to show the application in art and architecture of what may be seen in Nature. These problems deal with a variety of matters essential to the training of artists and draughtsmen. The book comprises 120 4to pages, with 108 illustrations. The price is $3.00 net.

PERSONAL.

Mr. W. E. Doran, architect, of Montreal, is again mentioned as a probable candidate for the mayor's chair in that city.

Mr. Lewis Maxwell, a pupil in the office of Gouinlock & Baker, architects, Toronto, who has recently been indisposed through lung trouble, is now sojourning at the Gravenhurst Sanitarium. His many friends will be pleased to learn that he is getting along satisfactorily.

The six most lofty structures in Europe are the towers of Cologne Cathedral, now 516 feet, 9 inches high; the towers of Rouen Cathedral, 491 feet, 8 inches; the tower of St. Nicholas, at Hamburg, 473 feet, 1 inch; tower of Anvers Cathedral, 472 feet; cupola of St. Peter's, Rome, 469 feet, 2 inches, and the cathedral spire at Strasburg, 465 feet, 7 inches.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited.

Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

John Goettsche, of British Columbia, is investigating the clay deposits in South Dakota with the view of erecting an extensive brick works in that state. Tests are being made of the clays in the vicinity of Brookings, and if the results are satisfactory a plant may be erected at that place.

A Small Sewage Disposal Plant of considerable interest is described in a recent issue of "Indian Engineering." It was designed by Mr. C. C. James for a leper asylum with 400 inmates near Bombay, where the sewage originally drained into two large cesspools. These became a nuisance, so a disposal farm was laid out with settling tanks for liming the raw sewage, but the lime injured some of the crops and it had to be abandoned. Finally the land became "sick," and the septic system was introduced preliminary to the land treatment. This has been successful, and the sale of the farm crops yielded last year a profit of 21 per cent. above working expenses. The septic tanks have a capacity of about 19,000 imperial gallons, and the sewage passes through them at a rate of about 20 feet an hour. The leathery scum on the surface is 1 to 3 inches thick and there is some sludge at the bottom. The septic effluent has been used in experiments with a number of filters. One which gave a good result was made with pieces of coal. Another filter which received raw sewage, was made of pieces of brick with pipes to distribute air through it in accordance with the principles advocated by Colonel Ducat. The sewage was 45 minutes in passing this filter and was well purified by the process.

Ivory Enameline

For Interior Use

This is the palest and finest varnish of its kind made. It is designed for the very finest

Architectural Work

And especially for natural woods. It will take a very high polish, which it retains for a remarkable length of time.

Zinc White ground in this varnish makes a pure white enamel which can be either rubbed to an egg-shell gloss or finished to a piano polish.

N.S.W. Industrial Arbitration Act

To the government of New South Wales belongs the credit of having departed from the beaten path in respect to legislation for the settlement of industrial disputes. The Industrial Arbitration Bill which has just become law, compels reference of all disputes between employers and employees to a competent court, with power to enforce its orders and awards, and makes a strike or a lock-out before or pending such reference a misdemeanor, punishable by fine or imprisonment. The court will be presided over by a Judge of the Supreme Court and will have most extensive powers, including the power to declare a standard wage, and to direct that, other things being equal, an employer shall give preference to unionist over non-unionist laborers. There is no appeal from its decisions. The result of the operation of this law will be watched with great interest, particularly by the great industrial nations.

Effect of Stock Speculation on Building.

THE American Architect states its belief that much of the indisposition manifested by small capitalists to invest in land and houses is due to speculation in stocks and the losses resulting therefrom. "Every one who takes note of the course of stocks," says our contemporary, "will remember shares which a few years ago were sold with the recommendation of bankers of the highest standing at fifty dollars, and after paying an assessment, could with difficulty now be disposed of at fifty cents, or a copper stock which has fallen within a few months from seventy-five to five dollars a share." There undoubtedly exists good foundation for the above opinion. Unfortunately Canada is following the lead of the United States in this matter. Our young men, especially business men of all ages and in every line—not excluding the professional man or even the preacher—are seeking wealth by a short and easy road. A few are succeeding, but the majority fail, and the community is poorer by the money lost in this way which should have gone into building improvements and other enterprises of a tangible character.

Importance of Proper Inspection of Building Work.

THE necessity for careful inspection of construction work on important buildings is exemplified in the case of an expensive city church, in the roof of which a number of leaks have developed. On investigation, it was found that the valleys extended only four inches instead of four feet under the slates, allowing water and ice to find access beneath the edges of the slates and destroy them. Two or three hundred dollars have already been spent on repairs and it is estimated that six hundred dollars more will be required to make the roof weather-proof. Another instance is that in which the authorities of a church are confronted with the necessity of lowering the furnaces in the basement in order

to make them comply with the insurance regulations, which provide that the tops of turnaces must be so many inches clear of the joists. The authorities must either lower the furnaces and piping at considerable expense, or run the risk of getting no insurance if fire should destroy the church. These buildings were constructed under the supervision of an experienced architect, who was probably too busy to watch the progress of the work in detail. Where such important interests are involved, however, the client has a right to demand that there should be careful inspection of the work if not by the architect, by his deputy or a clerk of the works.

Value of the Drop Test

THE increased use of iron in construction has drawn attention to the necessity of using other methods in addition to the tension test for determining the soundness and strength of materials. The value of the drop test in this connection is becoming more generally recognized. The usefulness of this test and the best method of conducting it are treated of in a recent paper by M. Ch. Fremont, in the Bulletin de la Societe d'Encouragement pour l'Industrie Nationale. The writer shows that the results are very different if a test bar is broken by a number of moderate blows applied consecutively or by a single heavy blow. He therefore insists that a drop test should be made by a single blow producing rupture of the test piece, in contradistinction to the method which has prevailed of preparing a number of similar test pieces from the same metal and subjecting these to a series of drops of gradually increasing height, with but one drop to each piece, until one piece is broken. M. Fremont has devised a system for measuring the residual living force in the ram after the drop has injured the test piece, the difference then giving the resistance of the material. As the result of experiments on more than ten thousand specimens he has decided to use a standard test piece 10 millimetres wide, 8 millimetres thick and 30 millimetres long. These dimensions permit specimens to be readily cut from boiler and ship-building plates as well as of heavier parts. In view of the importance of the drop test as an auxiliary to the tension test, it is desirable that in future specifications should demand the application of such a test in addition to the tensile test.

The Toronto Technical School.

The Toronto Technical School has become an expensive institution. A building was recently provided for it at a cost of nearly $100,000, and the running expenses have become a heavy item. The general taxpayers who have to provide the necessary funds, should be interested in seeing that the school is properly managed. The impression prevails that considerable bungling has taken place owing in part to the preponderating influence of members of the Trades aud Labour Council on the Board of Management. A radical change was recently made in the method of management, the services of a principal being dispensed with and the general management being vested in a committee. Each department of the school was placed in charge of an instructor, who in turn was made responsible to the committee. Judging by the determination of the committee to appoint a new principal, this plan seems to have failed. Prof. McKay, of McMaster University, was chosen for the position, but after having accepted, reconsidered the matter and decided to remain in his present position. The selection of a qualified person to become the director of the school is attended with difficulties and fraught with important consequences. Having assumed heavy financial responsibilities in providing a building, equipment and teaching staff, a successful result must largely depend on the selection of a thoroughly qualified manager. In addition to being familiar with all that has been done and is being done in the line of technical education on this continent and in Europe, he should have knowledge of the special requirements of a Canadian school, and what is still more important should have power to organize and maintain in highest efficiency the various departments of the school. It was doubtless unavoidable that mistakes should have been made in the initial history of an institution designed to impart instruction on new lines, and for the organization of which there were few precedents. This experimental period should now be nearing its close, however, and from this time forward it should be possible to proceed on more clearly defined and certain lines, and to achieve results which should justify the large expenditure involved.

TESTS OF PORTLAND CEMENT.

The purposes for which Portland Cement is employed are increasing so rapidly and the manufacturing capacity is developing at such an astonishing rate that there is greater need than formerly for methods by which the quality of the material may be speedily and accurately determined. Much attention was given to this subject by the International Association for testing materials, at its third Congress, held in Budapest last September. Among various papers on cement and cement testing, presented by members of the Association, was one on "The Constancy of Volume of Cements," by Mr. Bertram Blount, cement chemist, of London, Eng. The author suggested the adoption in quantitative form of a hot test for Portland Cement which in its qualitative form has long been in use in the construction of harbors and other public works, viz. :—A bar of neat cement is exposed to the influence of water at 45° C, and the expansion observed by means of the Bauschinger apparatus. A good cement should remain absolutely free from cracks, and should expand not more than 2 per cent. attaining constancy of volume in seven days. The application of this test to sixty-eight specimens of cement produced by five leading English manufacturers, gave satisfactory results in twenty-nine cases.

The president of the Association, Prof. Tetmajer, of Zurich, a high authority on the subject, stated that out of 127 specimens to which this test had been applied in his laboratory, only three had failed, and that the hot test for cement had already been adopted by the Swiss Federal government.

It is probable that a form of hot test will be included in the specifications for Portland Cement to be discussed at the next Congress which will take place in St. Petersburg in September, 1903.

After a lengthy discussion the Congress adopted a motion by Prof. Wm. Hawe of New York, for the appointment of an International Commission to collect so far as possible before the next Congress, material for establishing normal tests and specifications for Portland Cement, which may be used in international commerce.

THE AMENDED BUILDING BY-LAW OF TORONTO.

The Toronto Building By-law which has for so long a time been in retirement and understood to be in a constant state of revision has at length emerged from this lonely furrow and put itself at the service of the citizens of Toronto.

It is a remarkable by-law in respect that what there is not in it would make a fair-sized volume—and a very useful volume too. The law as it is given to us, deals chiefly with negations and even then it likes to be general. There is no doubt safety in generalities, to guard a position of power. For example, the opening clause of the by-law, the clause relating to the Inspector of Buildings, is admirable. It states simply that the duty of the Inspector of Buildings shall be "to see that the provisions of this By-law are carried out." This is simple, but comprehensive. It guards the power of the Inspector more effectually than the most elaborate definition of his rights. But, when we come to examine the provisions of the by-law, we find they are of the same nature—guarded rather than explicit. It is as if the authors of the by-law took the view that the municipal council is the natural enemy of building in Toronto, prepared only to swoop down upon it for offenses, instead of the view that the council are the city fathers, to lead intending builders in the way they should go to make the building of the city good.

One evil of a by-law full of generalities is the likelihood of conflict between builders and the Inspector, on the ground that where there are no definite directions the builder's opinion is as good as the Inspector's, and perhaps it may be. For example, under the head of Public Buildings, Sec. 31, it is provided that "no church, hospital, college, school, hall, theatre, or other building of a like nature used as a place of worship, or for public meetings of amusement or resort, shall be used or hereafter constructed unless the same contains such a number of doors, halls, stairs, stair railings or other means of egress "it is to be hoped this will not give colour to the idea that sliding down a handrail is permitted." of sufficient size and strength as in the opinion of the Inspector of Buildings shall afford ample facilities for free and rapid egress in case of fire, panic, or other cause." This is all very well, but public buildings are not erected by the "cut and try" method. An Inspector cannot come on the works of a public building in June and tell the architect that a passage-way he planned in January, must be a couple of feet wider. The plan is figured throughout to meet the existing dimensions, and the iron is all on the ground. The Inspector will either have no opinion upon that point, or if he has, and wishes to make it law, he must expect to find ample facilities afforded for his free and rapid egress from the building. This will not make for the authority of the law. It would be better if it was settled beforehand what is to be the standard in all cases where there can be the question of a standard. Then it will be known in advance what the opinion of the Inspector is going to be; and any dissent from it can be settled in advance, before the plans are made.

This would imply more work than the construction of the present by-law, but genius is not required; the process is one of compilation. If there ever was such a thing as a first by-law, no living human being has seen one. All bylawsare scompiled, and the process is commended to the city officials as a fascinating labor, in which perfection is attainable, and whereby they would learn a lot. Indeed it would not have been necessary to do so much work as might at first sight appear in order to fill in the deficiencies of this by-law, for the ground was well covered in a draft of by-laws, drawn up in 1895, with great care and many meetings, by a select committee of the Ontario Association of Architects, and placed in the hands of the City Engineer; among whose records it may doubtless still be found. That this draft was rejected by the revisers of the by-law argues that they aimed at something different, but it is difficult to see what they aimed at; it is difficult to grasp their purpose. If it is only a fire by-law, why enter into the question of the thickness of brick walls? If it is a building by-law, why not tell us some more? The thickness of a wall in proportion to its height is not the last word about building a wall. One of the notable building failures of New York was due to the quality of mortar used. There is not one word about mortar in this by-law. Nor is there anything said about the length a wall may run between cross walls or buttresses, for a given height; yet, even if this is merely a fire by-law, it is a consideration important for the safety of firemen that there should be some limit fixed in this.

The by-law should, in fact, declare the standard of sound building in all points. This sounds like a large order, but that it is possible is easily seen from the simple fact that it is done. The building by-laws of the great cities of the United States are compendiums of the art of building as locally practised. Indeed it is not necessary to go to the United States for example. The Montreal Building By-law is before us. It contains the usual precautions against fire, more complete than those of Toronto, where we have compared them. It contains also the rules for thicknessing walls, better stated than in the Toronto by-law because displayed in the form of tables, where the average sensual man can grasp them better than if, as in the Toronto by-law, he has to dig painfully for them in a six inch legal paragraph with one full stop. But it contains much more than this. There are full directions for building according to a standard of safety; and that is what we want in Toronto. The Montreal law takes hold of things from the very bottom by specifying the depth of the frost line; and from there up the builder has given him an authoritative decision upon every point, as to what constitutes good building. Footings, foundation walls, damp coursing, stone walls, brick walls, hearths and chimneys are all treated; and the different compositions of mortar are introduced in an intelligent manner as a condition affecting the loads permissible on walls. The strength of floors for buildings of every class, the strength of roofs of all pitch, are fully defined. To be

brief—for we write, not to praise the law of Montreal but to condemn that of Toronto—all questions of standard that arise in designing a building have in the building law of Montreal and other cities a minimum fixed by-law. The result is a sound handbook of building for these cities, and that is what we want in Toronto. For many men it will be the only handbook they recognize, and without it they have none.

As a record of the decisions approved by the general experience in building matters, such a by-law is uselul to architects as well as builders, not only to save labour but to save doubt and discussion ; to, in some measure, standardize processes which form so large a part of the investment of capital. The building laws of New York and Boston have before now been used in Toronto, as authorities for this purpose ; but a by-law of our own would be the proper authority.

In short the law is for instruction as well as reproof. If the whole object of the building law were to catch people tripping, it would be well to be as cautious and general as possible, and to give as little information as possible in order to catch the ignorant and unwary as well as the wicked ; but the object of the law ought to be to prevent people tripping ; to instruct the ignorant, warn the unwary, and leave the Inspector of Buildings to deal only with the wicked. That is his function and that is all.

To leave anything that can be settled beforehand, to be settled by the opinion of the Inspector of Buildings is nonsense. He is there to administer the law not to make it. The municipal council have power to make reasonable by-laws, but they have no right to delegate this power to anyone else. In making a by-law so general that it requires interpretation in detail, and in handing over the right of interpretation to the Inspector of Buildings they have in effect delegated to him the power of defining the requirements of the law. It is questionable whether this is a legal position ; it is certainly unpractical. The city of Toronto is still without a reasonable building by-law and something ought to be done to remedy this defect.

We want a precise and comprehensive by-law, printed in a convenient form, with tables, diagrams and cuts sufficient to make it plain, and an index. This is not much to ask for, but it would be a great thing to have.

EXPORT CONDITIONS AFFECTING HEATING APPARATUS.

A gentleman from Canada, intimately connected with the building business, visited the Glasgow Exhibition last summer, and on his return expressed disappointment with the character of many of the Canadian exhibits in manufactured goods. He instanced the case of radiators, in the manufacture of which Canada must be considered to be at the top of the ladder. The exhibit of these goods in the Canadian Building consisted of only a few radiators placed in an out of the way corner. The same gentleman made unfavorable comparison between our exhibits of stoves and those of British manufacturers, stoves being another line of manufacture which has reached great perfection in this country. He further stated that the American radiator manufacturers had captured the British market, and, to a large extent, driven out Canadian radiators.

In response to enquiries on the subject, we find that the small exhibit of radiators in the Canadian Section was placed there by request of the Canadian Commissioner, and that accommodation could not be given Canadian manufacturers in this building to make an adequate display of their goods. Another exhibit in this line was made in the British Section in the name of Messrs. T. B. Campbell & Sons, of Glasgow, who are agents for the Dominion Radiator Company. It is to be regretted that in lines of manufacture in which we admittedly excel, we should not have had proper representation. A manufacturer who visited the Exhibition informs us that the nations that had the fewest exhibits, such as Russia and India, appeared to have the most space, far more in fact than they required, while Canada, which is an important part of the British Empire, was not given room enough to fairly display her goods. Attention was recently called to the fact that a creditable display was not made in the Canadian Building at Buffalo, that Canadian exhibits were scattered about in the various buildings in such a way as to make it impossible for the visitor to receive a comprehensive idea of our development in various lines. The same objection seems to hold good in the case of the Exhibition at Glasgow. It is to be hoped that if Canada is to be represented at future Exhibitions of this kind, the Government will see to it that adequate space for the purpose is obtained, and that the exhibits are displayed to equal advantage with those of other countries.

As regards the competition of American manufacturers of radiators in the British market, we learn that a large share of the trade in this line is being secured by the United States. This is chiefly due to two causes, first, the advantage possessed by American manufucturers over those of Canada in carrying charges. By taking advantage of cheap transportation by canal from Buffalo to New York, and from thence chartering schooners to carry their goods at very low cost across the Atlantic, United States manufacturers are able to sell in the British market at lower figures than Canadians are willing to accept. To assist them in maintaining their advantage, these manufacturers are now bringing iron from the Dominion Iron & Steel Works, at Sydney, Nova Scotia to Boston, at a cost for freight of only 70 cents per ton. On this iron a duty is paid of $4.00 per ton, 99 per cent. of which is however, refunded, on the manufactured product of the iron when exported, so that the Boston manufacturer effects a saving of $3.00 per ton in freight charges by using Canadian instead of American iron.

The manufacture of radiators in the United States is in the hands of an immense trust whose aim is to keep in operation their extensive factories. For this purpose they have apparently determined to secure the trade in Great Britain at all costs. Extensive showrooms and warehouses have been opened in London where a large stock is constantly carried, from which orders can be filled instantly.

Notwithstanding Canadian manufacturers are getting a considerable amount of export business, and are at present favored by the fact that for the first time in many years iron is being sold in Canada at $2 per ton less than in the United States. The demands of the home trade have been so great as to keep factories here running at their highest capacity. Under these circumstances our manufacturers are not disposed to sell their goods in Great Britain without a profit.

BY THE WAY

The law under which gardens and pleasure grounds in France have been exempt from taxation, has been repealed. It is feared that the result must be the filling up of such spaces with buildings greatly to the detriment of beautiful cities like Paris, which has become the admiration of the world largely in consequence of the encouragment given property owners to beautify the surroundings of buildings.

× × ×

The heart of the architect and builder, who happens to have any work to do, and the majority have, has been gladdened by the unusually delightful weather that has prevailed throughout the autumn and thus far into the winter. The click of the roofer's hammer and his merry whistle may still be heard in many directions, having outlasted the twitter of the birds whose instinct impelled them to migrate southward. Not only is advantage being taken of the favorable weather to finish up outside work on buildings in the advanced stages of construction, but during the last month work has been commenced on quite a number of new projects, the foundations of which will at least be put in before Jack Frost puts his temporary veto on the proceedings.

× × ×

I am pleased to observe that as the result of numerous complaints from citizens the City Council of Toronto have requested the City Engineer to report on the advisability of erecting a stand pipe to draw off the gas from the Yonge Street sewer and prevent its escape at the street gratings. Some of the north-end streets are even worse than Yonge Street, and in the interests of public health, means should be found of preventing or reducing to a minimumthe countflow of gas at the street level. There is little doubt that contact with this foul escaping gas has been the cause of much sickness. The evil, which is aggravated in cold weather by the difference in temperature inside and without the sewers, should be remedied. Half a dozen stand pipes would doubtless effect a cure so far at least as the northern part of the city is concerned, which district on account of its higher elevation, is most affected. Objection has been made to the erection of stand pipe ventilators on the ground of their unsightliness. It should be possible however to place them alongside the poles carrying electric wires or in some equally inconspicuous position. In any case much as we should regard the good appearance of our streets, the protection of the public health is a matter of even greater consequence.

× × ×

It is perhaps ten years ago since the city of Ottawa commenced the erection of a hospital for the treatment of contagious diseases on Porters' Island. The structure was so wretchedly built that it had to be abandoned. The Council then began casting about for another site. One after another was chosen only to be abandoned in the face of injunctions secured by owners of adjoining properties. So matters have gone on year after year even until the present time, and the end is not yet. Even the presence of smallpox which is reported to be prevalent in Ottawa at present, does not appear to hasten the progress of the project. The undertaking will probably await the advent of another generation of aldermen, who starting de novo, and undaunted by the recollection of past failures, may succeed in carrying it through.

ORGAN CHAMBERS AND CASES.

Canadian architects will be interested in reading the suggestions for the proper installation of pipe organs in concert halls and churches, as given by Mr. Chas. F. Brindley, member of a well known British firm of organ manufacturers, in a paper read before the Sheffield Society of architects and surveyors.

Dealing first with the placing of organs in concert halls, the best position for the organ was at the end of the orchestra. Special attention should be given to allowing ample space, so that the organ may be built on one level, in order that it may be affected by changes of temperature and so thrown out of tune by the consequent expanding of metal pipes, which occurs when instruments are constructed at different heights. In providing for machinery for blowing care must be taken that (a) the room be dry ; (b) within reasonable distance of the organ proper ; (c) the temperature be the same as that of the hall.

Dealing next with the placing of organs in places of worship, the lecturer stated that lack of space allowed and disregard to all proportion were the greatest evils. The placing of the organ on a screen dividing the nave from the choir was undoubtedly the best, but is unfortunately seldom adopted and favoured by modern architects. Putting an organ in the west gallery is highly recommended by many experts. An organ chamber was not a good place for an organ. If this latter method be a necessity, the lecturer pointed out that it devolved upon the architect to design such chamber so as to mitigate the evil as much as possible by providing plenty of space, making it of sufficient height, and having ample opening into the church for the ingress of sound.

The government of Quebec will invite the artists of the province to submit designs in competition for an historical tableau with which to decorate the assembly room of the Quebec legislature. A prize of $2,000 will be offered.

COLOUR IN ARCHITECTURE.

Mr. A. Wallace Rimington recently presented a suggestive paper before the Architectural Association on "Colour in Architecture as seen through an Artist's Glasses." We lived, he said, at a time when from various causes the colour sense of civilized Europe had seriously deteriorated, and when, although there was some slight revival or new development of the feeling for colour amongst the cultivated few, it was, perhaps, becoming more and more weakened or obliterated amongst the great majority. Taking a general view of Europe, and, excepting this partial revival, it was difficult to avoid the conclusion that in decoration, in costume, and in the thousand small objects of everyday life colour tended to disappear, and, speaking broadly, where it remained, to become more crude and less harmonious.

In Architecture, as the oldest and possibly the greatest of all arts, the study of colour could not, of course, be neglected. Whether we liked it or not, it must come into play more or less in every building. "All materials possess colour of some kind, and this colour directly affects the impression produced by a building. Moreover, the good effect of any architectural work, fine in respect of proportion, line and detail, may be completely destroyed by a vulgar colour scheme, with bad divisions of its colour masses or inartistic colour accentuation of unimportant parts; whereas, on the other hand, harmonious and refined colour may, as we all know, add immensely to its interest and dignity." He admitted that the whole question of colour was surrounded by great and special difficulties. Colour was, however, quite as difficult to deal with as musical sound, and probably much more so. It was not easier to strike an absolutely true colour note than to sing a musical one, and the colour scale had longer and more subtly graduated vibrations. Every good picture was a series of colour chords, carefully selected and combined, and it might be asserted that every building ought also to be, even though its colour harmonies may be simpler.

Dealing with the principle that the richest colours should be in the halt tones, and applying it to architectural design, Mr. Rimington contended in exteriors, in which varied colour enters, it would indicate the undesirability of putting a weaker colour into a cornice immediately under the eaves of a building, into the under-cut portion of a projected moulding, or into any hollowed or shadowed surfaces, rather than into those exposed to the full strength of the light, conversely if it were desired to strengthen the general colour effect it would be well to enrich the former with relatively strong and warm colour. One was often struck, from the painter's standpoint, by the way in which a building of warm-toned material had been made unbearable to the artist by the shivering coldness of its painted woodwork, just where the eye, accustomed to Nature's methods, would expect additional warmth and richness. Examples of the advantage of keeping recessed mouldings warm and full in colour might easily be found in the mixed brick and terra-cotta architecture of Italy, especially of such districts as those of Pavia, Milan, Bologna, and Brescia. In the church of Chiaravalle warmth and richness of colour were throughout introduced into the shadowed mouldings and cool coloured materials were always avoided in them; and the same thing applied to the exquisite little campanile of San Gottardo at Milan.

Referring next to the twin principles of "inter-contrast" and "quality:" the interweaving of divergent colours which tended to make them appear pure and luminous, and "quality," a vague term which might be roughly defined as texture, he said it was obvious that these two sister principles were also very applicable to colour in Architecture. One sometimes saw a building or part of a building which was interesting in its forms and detail, and at the first glance was not absolutely bad in colour, and yet one felt it was monotonous and unsatisfactory, and that it would be impossible to sit down and paint it. One asked oneself "Why?" and one discovered it was because its colour surfaces were dead and uninteresting, and because there was no play of intermingled colour and no "quality" in them. As texture so much affected colour, the architect could by using varied and contrasting surfaces make the colour of his stone, brick, metal or other material more pleasing to the eye. If this applied to exteriors, how much more to inferiors. There the architect had endless opportunities for producing colour which should be real colour and of educating the colour sense of his clients. Paint, distemper, and other stains, gilding, coloured materials of all kinds, gave him a palette almost as rich and varied as that of the artist.

Gradation, "focusing" and contrast were dealt with in turn. He had seen many charming examples of the latter in architecture in Italy and Spain and in other parts of Europe. The harmonising effect of the detached and isolated points of strong colour in many Moorish and Arabic buildings was often delightful. Skilful contrast of colour would seem to be of special use in architecture where the building itself was relatively uninteresting. Mr. Rimington submitted that as harmony of colour was of the first importance in painting, it was also of the first and greatest importance in colour as applied to architecture, and in much of our modern work was insufficiently studied. Sympathetic study of harmonious colouring would seem to be as needful for architects as it was for painters; and as it was now mainly a matter of artistic feeling—he put in a plea for the study by architects of the great masters of colour in the sister art of painting.

Whatever architecture might have done in past the for the development of the colour sense, it had it in its power to do much more in the future. Architecture was the one art with which all classes were in contact, and which perhaps more than any other had the opportunity for silently presenting and interpreting beautiful form and colour to them. Those amongst painters who loved and reverenced good architecture with an intensity which could not be put into words, and who had drawn so many of the great buildings of the past with a thrill of enthusiasm they could never forget, sometimes had visions of cities in which every building should be full of interest and beauty, and in which colour should play an infinitely greater part in architectural design than it did at present.

Mr. W. F. Harper, architect, of New York, formerly of Barrie, was unexpected called home by the death of his brother the late Mr. H. A. Harper, who was drowned while heroically attempting to save the life of Miss. Fielding at Ottawa.

O.A.A. CONVENTION.

The annual convention of the Ontario Association of Architects will be held on Tuesday and Wednesday, January 14th and 15th, 1902. The Council has made arrangements for an interesting programme of papers and discussions and hopes that every member will attend and that this will be a representative gathering of the architects of Ontario.

Besides important matters of business, papers will be read by Dr. P. H. Bryce, secretary of the Provincial Board of Health, on "The Disposal of House Drainage in Localities not having Sewers;" by Mr. C. H. C. Wright, on "The Behaviour of Steel under Stress;" by Prof. Capper of the Department of Architecture of McGill University, Montreal, on "University Training in Architecture," and by Prof. Warren P. Laird of the Architectural Department of the University of Pennsylvania on a subject not yet announced. The Council will be pleased to have the attendance of all architects of the city and province.

ARCHITECTURAL EDUCATION.

The importance of providing means for the thorough education on proper lines of architectural students is every year becoming more clearly manifest, and is receiving increased attention at the hands of the governing bodies of architectural societies in Europe and America. In his recent address to members of the R.I.B.A., the president, Mr. Wm. Emerson, gave expression to his views on this subject, in terms following:

"One thing on which all who are experienced in the training of the human mind are agreed is that a good general education must precede special knowledge. This is an axiom which guides your committee in their educational work. It finds expression in the large number of subjects we provide, all of which we consider it of importance that every architect should be acquainted with. It is essential that our curriculum should aim to be comprehensive, to lay a good foundation of general architectural education which will fit men to adapt themselves as readily as possible to the special line they may wish, or be compelled to adopt. If your foundation is not sufficiently deep and wide you will sooner or later show signs of settlement. So much for our successful past and hopeful present. I will now with your kind indulgence deal with what I am persuaded we ought at once to take in hand. I refer to the establishment of day courses of instruction, and I will give you reasons which I think will commend themselves to you as indisputable. Not that I claim orginality for this idea. It has, like almost every other subject which affects the profession, been discussed many times by your Committee, but dismissed for the time being mainly on financial grounds. In the first place, our system of pupilage—necessary and excellent as it is in principle—is still admittedly and radically faulty, from the standpoint both of the master and of the apprentice. The former is too busy to undertake the pupil's education; it is as much as he can do to give him the run of his office, to allow him to spoil material and waste his paid assistant's time in gleaning what knowledge he can. The latter finds himself irrevocably bound to serve at least three years, even if he discovers within the first few months that he has mistaken his vocation. A two year's full course of study in a purely architectural college, controlled by experienced architects, would obviate both these objections to the present system without in the least endangering it and I am sure that most architects in practice, and probably every Fellow of the Royal Institute of British Architects would, as an encouragement to a movement which would secure useful servants from the first, not only agree to accept a rather smaller premium, but probably also to a less lengthy apprenticeship. The pupil, on the other hand, would as a rule discover during his first two or three terms in such a school whether he was fitted for the work, and would be free to drop its further pursuit without loss of time or premium. It would be a truly advantageous arrangement to both parties. With the exception of the Victoria University at Liverpool, I believe King's College is the only institution in this country which has an architectural day school, but King's College architectural course appears to be a department of what is really an engineering school.

THE EARLY ENGLISH CATHEDRALS.

Public interest in and appreciation of good architecture must undoubtedly receive a stimulus from lectures such as the one delivered at Victoria College, Toronto, a few evenings ago, by Rev. Prof. Cody, entitled "The Early English Cathedrals." Even a brief contemplation of the many beautiful examples of architecture thrown upon the screen, and of the explanations given regarding the characteristics and development of the various periods and styles, must lead to results in this direction.

Beginning with the Norman period, the lecturer traced the development of ecclesiastical architecture in England through the Early English Decorated and Perpendicular periods. Reference was made to the contrast in purpose and design between English and French cathedrals. The former were primarily built for the clergy, the latter for the people. Hence the English cathedrals are usually surrounded by open spaces, schools and dwellings for the clergy, while as a rule, the French cathedral is situated in the heart of the city closely encompassed by shops and dwellings. In design the English cathedral is low and broad, the French high and flamboyant, like that at Rouen.

The audience were shown by means of excellent lantern slides in the hands of Mr. Robert Parker, exterior and interior views of the great cathedral churches of England, from Canterbury and Winchester to St. Paul's, but strangely enough were given the name of only one architect, Sir Christopher Wren, who is said to have received for his services the munificent sum of £200 per annum, for which as he said he "consented to be hoisted three times a day to the top of the dome, at great hazard to his life."

THE P. Q. A. A.

The Annual meeting of the Province of Quebec Association of Architects will be held in the City of Quebec on Friday, January 24th, 1902. The Counci has been called to meet on January 9th to complete the programme.

Mr. William Emerson, President of the Royal Institute of British Architects, has been elected an honorary member of the American Institute of Architects.

MR. RUSKIN AND ARCHITECTURE.

Sir W. Martin Conway, who has been elected to the Slade Professorship of Fine Arts, at Cambridge University, for the usual term of three years, made some suggestive remarks on the occasion of Prof. Petrie's lecture on Egyptian architecture. He confessed that as he watched the slides upon the screen and listened to what Prof. Petrie said, it occurred to him how very strong an illustration he had shown them of one very interesting fact which he thought might be observed throughout the whole history of architecture, and that was how frequently architecture styles had arisen from the exact contrary to the statement made by Mr. Ruskin. He meart the imitation in one material of forms devised for another. He rather thought it was one of the axioms of Mr. Ruskin that nobody should ever do any such thing as to imitate in one material decorations which were prepared for another. But in the history of architecture he believed it had always been the case. Styles had been developed by doing the very thing deprecated by Mr. Ruskin. In the earliest form of architecture, which they had now had revealed to them, they had the very beginnings of stone architecture—or, at any rate, of the decorative forms used in the earlier stone architecture—derived by direct imitation from the old forms developed when the material of building was not stone. And just that occurred then, so it occurred in Greece when stone architecture arose, by the imitation of the forms devised for wooden architecture. He thought they might take the lesson to themselves in the present day, because they were living in an epoch when exactly the same thing was taking place. They saw the metal construction coming in and about to become the dominant constructive feature in all the architecture of the world. He noticed the other day in New York—and he supposed every one had noticed it—that in the great buildings which were really metal buildings faced with other material, the architectural forms were all imitations of those forms which were devised as decorations or even, as structural features in old stone buildings. So in the present day they saw going on exactly the same architectural process of development which had been illustrated that night in the extraordinarily interesting beginnings of architectural art described by Prof. Petrie.—The Architects' Magazine.

SAFETY OF THEATRES.

In opening a discussion on the subject of the London County Council and Theatres, Mr. Edwin O. Sachs the well known theatre architect of London said the countries of Europe and the Western Hemisphere had every kind of legislation conceivable for the protection of the public. It was really time for some representative body of experts, officials, managers and business men to decide as based upon the experience of the great cities of the world generally, what was really essential, and then to see to what extent the world's wisdom could be applied to the best advantage of Great Britain and the Metropolis in particular.

To my mind, continued Mr. Sachs, the clear planning in a theatre is of greater importance to the audience than clever fire-resisting construction, and the regular attendance of reliable fire-watchers day and night and especially during the performances, is more essential than any amount of surprise inspection; but these are only personal views. I consider the order of precedence for theatre safety to be :—1, straightforward planning; 2, regular watching; 3, skilled inspection; 4, good construction. The protection of life by means of rapid exit, should always have the first place. I have been over many theatres built according to modern regulations, of the best fire resisting materials, and yet have found them dangerous in the extreme, through bad arrangement of staircases and passages. As to our latest London County Council theatre regulations for new buildings, although they contain much that is extreme on the one hand, and neglect some points of vital importance on the other, they are in many respects model ones, and speaking generally, both the playgoer and the aspiring theatre builder can be well satisfied with them.

In conclusion, Mr. Sachs proposed that the Lord Chamberlain should appoint a special commission, which should draft some practical scheme by which the essentials of theatre safety might be obtained, and some practical scheme for control and administration be formulated.

NOTES.

The Annual Architectural Exhibition of the Philadelphia T Square Club will be held from the 4th to the 18th of January.

The first of a series of lectures on art under the auspices of the Ontario Society of Artists was given recently by Mr. B. E. Walker, his subject being "The Early Italian Painters."

The owner of a recently completed apartment house building in Chicago states that by the expenditure of $8,000 in fireproofing materials, he secured a higher class of tenants at an averaged increased rental of $5 per month for each apartment above the highest rental anticipated before the change in the specifications was made. This increased rental amounted to $1,680 per annum, or 19¼ per cent. on the amount expended for fireproofing.

The interesting experiments originated by Prof. Hele-Shaw for studying the motions of a fluid are being followed by somewhat similar investigations into the movements of air. The apparatus and the method are the invention of M. Marey, a member of the French Institute, and seem to have been inspired by Prof. Hele-Shaw's system. M. Marey makes the movements of air, contained in a suitable glass-sided box, visible by injecting numerous jets of smoke which form planes laminating the air. The results are photographed by the aid of a magnesium flash light.

The excavations were commenced lately for the foundations of the memorial to Charles Garnier at the Rotunda of his principal work, the Paris Opera House, but a further delay in the progress of the work is inevitable. It appears that the site selected was used for one of the builder's workshops, and for a depth of about 7 feet debris and fragments of stone were met with. With such a foundation it would not be possible to support a heavy memorial of bronze and granite. It will therefore be necessary to carry up the foundations for about 20 feet, and as they will be in solid masonry and the space is limited, the time occupied may extend to months unless extraordinary expedition is used. It is therefore possible that the memorial will not be inaugurated until 1902.

The City Engineer of Toronto has reported on the cost of the project to construct a driveway three and a half miles long and 100 feet wide along the lake front west from Bathurst street. Cribwork would cost $225,000 and a breakwater $160,000, the space inside cribbing to be filled in with street sweepings. The engineer reports that the work could be gradually carried to completion. It is to be hoped that the project will not be lost sight of as many others of equal importance have been. Centre Island is an example of what can be done with a comparatively small expenditure each year. The proposed driveway would add in a wonderful degree to the attractiveness and popularity of the west end. Owners of property in that locality could afford to pay a special tax towards the cost of an improvement which would greatly enhance the value of their holdings.

NORTHWEST CORRESPONDENCE.

WINNIPEG, December 5, 1901.

For some time past the question of erecting a large apartment building in the city has been before the public. The proposal has now taken definite shape and is being promoted by Hunter, Cooper & Co., financial agents, of this city. The intention is to erect the building on Ellice avenue, close to Knox Church. This is a good location and not far from the main portion of the city. The frontage will be 200 feet and depth 120 feet. Mr. E. Kennedy, of Minneapolis, U. S., is the name of the architect which appears on the sketch plans.

It is intended to put up a modern and thoroughly equipped building in all points, and first-class both in construction and finish. The outline plans show a structure in the form of the letter E. The main entrance is from an open court in the centre between the two arms of the letter, and is carried up to the second story, the doorways being flanked on either side by massive columns and pilasters of stone supporting a stone entablature. The building is seven stories in height above the basement, with an eighth story over the centre portion. The facade is to be of red pressed brick with diagonal work of a darker colored brick for the first two stories, Bedford sand stone dressing to windows and other openings, with a generous treatment of carved and ornamented work.

From the main hall, entrance is obtained to two large electric elevators, one on each side of the entrance, running from basement to top flat. The main or public corridors branch off on either side of this entrance, and at the turn or arms of the letter E the main stairs are located, one flight at each arm between brick walls. This arrangement is followed out on each floor. Private halls lead off the public corridors into the various suites of rooms. Each suite of rooms or household apartments contain dining room, parlor, library, kitchen, three chambers and bath room. All these rooms—in fact, all the rooms in the building—are lighted from the outside, the use of light wells being done away with. Some portions of the floors are to be laid off in smaller suites, such as bachelor apartments, doctors' or dentists' offices and artists' studios, the whole building having about 500 rooms.

Each suite of rooms as may be required will be provided with spacious cupboards, linen closets, store rooms and pantries, with cold storage section to be operated by an ammonia process located in the basement. Dust chutes when necessary from the rooms and floors descend to the basement and these will be of the most approved pattern.

The floors will be of fireproof construction throughout, overlaid in private halls and rooms with hardwood flooring, and the corridors will be paved with mosaic.

The bath rooms will be provided with enamelled baths, Syphon jet closets and marble wash basins, having hot and cold water, the sanitary arrangements being complete in all details.

The lighting, heating and ventilation will be of the latest description. Electrical heating is under consideration, as electricity will be supplied in the near future by the water power at Spruce Falls, sixty miles from Winnipeg and at a very reasonable rate.

The eighth story over the centre portion of the building is to be arranged for a restaurant, having general and private dining rooms with all the modern conveniences attached to same.

The basement is laid out for lockers, store rooms, bicycle rooms, etc.

The estimated cost of the completed building is $175,000, and if the plan is carried out as outlined it will be an enterprise of no mean order as well as an ornament to our city and will largely take the place of first-class hotel accommodation which is at present very deficient.

The past season has been one of substantial progress and activity in the building trade. Many large and handsome structures have either been begun or completed, and we find our city is so much the richer, not only in bricks and mortar, but also in architectural adornment. Building permits covering buildings completed or uncompleted have during the past year been issued to the amount of about $1,500,000.

At the south east corner of Main and Lombard streets, the Merchants' Bank of Canada are erecting a massive and handsome structure to be used for their banking business and for general commercial offices. The walls are up to the roof line and it is proposed to close the building in for the winter and complete next year. The structure is seven stories in height above the basement. The base for about five feet above the pavement is of grey granite and above this to the height of the banking floor the two fronts are of white sandstone. From this point to cornice line red pressed brick has been used with a liberal proportion of white sandstone in ornamental and constructional work designed and detailed in the Renaissance style. The columnar effect just below the main cornice is very striking. The Roebling system of fire-proof construction is to be used for floors, etc. It is by far the highest building here and when completed will form one of the most attractive architectural features of this progressive metropolis of the West.

Other banking corporations have not been behind in providing adequate and attractive buildings for their headquarters. During the year the Bank of Commerce, Dominion Bank and Bank of Hamilton have each shown their faith in the present and future prosperity of this land of promise by expending large sums of money in the completion of beautiful and stately edifices. The Bank of Commerce building is designed after the Corinthian style, constructed of light sandstone. Carefully designed and well executed details mark this structure as one of classic outline both as to elevation and internal arrangement. The banking room is lofty and a circular treatment has been adopted for the banking counter.

The Dominion Bank is modelled after the Renaissance style in red sandstone and terra cotta and is situated at the south-west corner of Main street and McDermot avenue. The general elevation is not as pleasing in outline as we could have wished and for a corner building is in our judgment, not high enough. The banking room is very lofty, but has somewhat of a cramped appearance. Excellent taste has been displayed in the elaborate finish of the entrance corridor.

The Bank of Hamilton building has been extended this year, doubling the size. The facade is of white brick painted, ornamented with red sand-stone trimmings in bold detail, making an imposing structure at the south-east corner of Main street and McDermot avenue. The internal finish, which is quartered oak, is to be completed this winter.

The Lake of the Woods Milling Co. have erected on McDermot avenue, in the rear of the Dominion Bank, a solid and commodious office building 2 stories in height, designed and executed in brown and red sandstone and pressed brick. The walls are lined and the partitions formed of hollow terra-cotta brick. The floors are fire-proof. The internal finish is to be of the best.

A local syndicate has erected at the corner of Albert street and McDermot avenue an apartment block called "The Alexander." The lower portion is divided into stores with plate glass fronts. The super-structure is of solid brick veneered with dark red pressed brick ornamented with buff stone trimmings. The two stories above the store fronts are almost entirely carried on steel beams supported by iron columns. The face wall above the window openings is carried by steel lintels, so that there is a continuous line of brick without arches. The two upper flats have been arranged for small suites of rooms, such as bachelor apartments. These are well planned and fitted with all necessary sanitary improvements.

The School Board have erected in Nena street, at the head of Notre Dame avenue, a large and handsome solid brick school of 12 rooms, with pressed steel ceilings. The building is complete in all sanitary and other appointments.

The Toronto Crematory Co. have just completed for the city a large crematory, having 3 furnaces with water grates. The chimney for carrying off the gases is 80-feet high. Tests are just now being made as to the efficiency of the furnaces to completly destroy garbage and other like material.

Winnipeg has grown and is still growing. The foregoing is but a glance at a part of what has been done.

Space would not permit to give a detailed list of the many wholesale warehouses, stores, commercial buildings and dwelling houses which have been erected during the year; suffice it to say that the expansion of trade and general financial advancement of the city fully warrant the outlay, and we look forward to the coming year as one of still greater expansion.

The premature cracking of varnish is due, more often than not, to iuquality of elasticity—to oily or improperly adjusted undercoats. Apply color that dries quick enough to become hard before varnishing over it, and so far as that color is concerned there will be no shrinkage sufficient to disrupt the varnish.

STUDENTS' DEPARTMENT.

THE TRUE AIM OF THE ARCHITECT.

There was much sound advice expressed in admirable style in a recent address, "To the Younger Generation," which Mr. Heathcote Statham delivered before the London Architectural Association School of Design. At the outset he exhorted his hearers not to accept the pessimistic views of those who maintain that all architecture is a sham and a worked out thing now, and that nothing but an entirely new beginning on a new basis can revive it. Architecture is no worse off now than it has been at any time since the Renaissance, as far at least as its higher possibilities are concerned. It is true that it is on a radically different basis since the Renaissance ; but we cannot help that. The Renaissance theory of architecture is not so contemptible after all. It might even be argued that it is the higher theory ; that we have exchanged the pursuit of architecture as a craft for its pursuit as an intellectual problem and we have developed in these latter days much more power of invention and much more sense of character in decorative detail than the men of the Renaissance possessed.

The lamentations made by what may be called the socialist school of critics over the supposed death of architecture are to my mind as unreal as their remedies are unreal. Architecture is not a dead art unless you choose to make it so. The more earnest and enthusiastic of the younger generation have had it so preached to them that architecture is dead, and that copyism has killed it, that they are all on the qui vive to do something original, as they think ; something picturesque ; something out of the common. Hence all kinds of vagaries—short stumpy columns, windows in unexpected places, immense rustications enclosing half the shaft of a column and leaving the other half bare, and so on. These devices do impart what is called "character" to a building, no doubt, as long as they are novel ; but one very soon gets tired of them. It is possible to be picturesque, no doubt, without being eccentric ; but it is a question whether the picturesque is the true object of architectural design. The picturesque, really and truly, will only come unsought ; a sought-out and carefully contrived picturesque defeats its designer's ends. A good deal of the work which an architect is called on to do in practice has not, unfortunately, much relation to art in its higher or intellectual sense. The whole thing is mixed up with practical requirements, sometimes of a very prosaic order. But when we can get the opportunity to contemplate and treat a building, large or small, as a whole ; a building the uses of which are associated with some of the higher objects of our lives—with the repose and sanctity of life, as in the house—the aspiration to higher life, as in the church—the dignity of corporate life (or, shall we say? the dignity which it should have) as in a municipal building ; in such cases it is the part of the architect to make of his building an embodied idea—a conception which should be whole and complete in itself ; a leading idea, pervading first the plan and expressed with the same completeness in the design. This is where I think that architecture is or can be still a living art. It is all very well for the pessimists to accuse modern architecture of being only a copied architecture, making use of the detail of preceding styles ; it is not within the power of man to avoid that, except to a very limited extent. Even before the Renaissance made such a radical change in the situation, the detail in each generation or in even fifty years, depended largely on that of the preceding fifty years.

It is in this matter of unity and completeness of idea in architecture that I think we get a valuable lesson from some of the Renaissance architects. What strikes one in the works of Inigo Jones and Wren especially, as compared with most modern work, is the manner in which they grasped the conception of a building as a whole, and subordinated everything else to a central idea. Every church of Wren's, for instance, is a distinct conception with a dominant idea of its own. The details they used were to a great extent borrowed (though Jones put some originality into his), and the decorative details, in Wren's buildings at all events, are often not good, and perhaps he was not much responsible for them; but their general conception of a building was nearly always fine and always complete and consistent with itself ; an architectural whole. The pessimist critics deny that architecture is anything but building, and are always dinning into us that drawing is not architecture. It is not ; but it is a means of showing and putting on record an architectural conception. An idea in architecture is an idea, whether carried into execution or not. As to the use of the detail of a past style, probably the wiser course, and the one that is most in accordance with the actual tendency of architecture in the past, is not to throw overboard the historical detail, but to regard it as a basis for gradual development and modification, little by little, as we find opportunity ; which is the way in which all the changes of style in the pre-Renaissance period really came about. They were not the result of sharp and sudden and wilful change, but of gradual modification.

Coming to another point, not to scruple to find fault with an old building because it is old, Mr. Statham said there is a weak tendency among modern architects to admire everything in an old building, instead of considering it on its merits as they would a modern building. Then the next thing to this blind admiration is blind imitation. The designers of old buildings were subject to human error like ourselves ; and a study of them critically, considering what are their merits and what are their mistakes, is far more useful to our minds than accepting everything as right because it is old. Two other reflections were added in concluding, first not to be sure that you are right in architecture and everybody else is wrong. There is a tendency to this among our young architects, partly arising, perhaps, from the fact that our aims at present are rather uncertain and conflicting.

The other observation is to make perfection in architecture for its own sake an object, and not for what you can get out of it. If those who make the love of the art rather than the desire of gain their first object—if they must be content to see others richer than themselves in bankers' balances they have the compensation of keeping their youthfulness of spirit and their appreciation of the beauty of life.

The demand for paints and varnishes is said to be greatly increasing in Japan. Formerly, stains were principally used for all timbers used in the construction of buildings, but of late the application of oil paints is coming more and more into favor.

AMERICAN AND CONTINENTAL HEATING PRACTICES AND APPLIANCES.

A writer who signs himself a member of the Royal Institution contributes the following on this subject to the London Plumber and Decorator :

We are apt to look to America for improvements and go-aheadness in heating, and we do not look in vain by any means; but how few know, or even think, that on the Continent, in France and Belgium, and only a few hours from London, steam heating systems are erected in business premises and in private residences in a more advanced and perfect manner than America can boast of. In these countries so near home the valves to steam radiators can be worked to control the supply of steam and regulate the heat to the greatest nicety, whereas, in adopting American methods, the radiator valve has to be full open or quite shut ; regulation of steam supply and heat is not possible. These remarks refer to the ordinary methods practiced in each country. England, it must be said with regret, is, in a general sense, behind both.

America is the home of the radiator, and it may even have originated there. Certainly the practical and pretty designs came to England from that country, and two or three (no more) English makers were stimulated to set to work and improve on what had served our purpose in the past. They have succeeded in this, but radiators of American manufacture still sell in this country by the thousand feet for every hundred feet of the home made article. The lesson to be learned from this is that more can be done by our manufacturers, but it needs funds, skill and smartness all on a liberal scale.

We had radiators in England before America invaded our trade, and the same radiators are still made and sold, but they had simply to subside into the rear when the others came, and there they remain. The demand for radiators in this country is worthy of a big effort, for it is an established demand and must grow greater. Radiators must be of a style or character which will serve to make them pleasing, or at least, not unsightly in nice rooms. It is in this that our rivals have succeeded chiefly.

The coming of the American radiator has been a blessing in disguise, quite apart from its stimulating our manufacturers. What it has done is to greatly stimulate the calling of the heating engineer. Residence work is now quite common and to be readily obtained, compared to what it was previously. The radiator has made this mode of affording warmth more acceptable, and, not least important, it has made it cheaper for given results.

Not only has America sent us its radiators, but the valves and fittings, the "trimmings," as they call them, have come also. They brought us the angle-valve and the union-elbow, two details to be grateful for, allowing, as they do, for very neat and unconspicuous connections at the radiators. They also brought us the floor plates and many little details which are gradually melting the average woman's opposition to a hot water heating plant in a house. It will not do to make the appliances and the work savour so strongly of the engineer's shop and the foundry. This has been a blight, dwarfing the growth of the industry ever since it originated. The Americans undoubtedly cured this.

It was America that we had first to thank and then to hate for the malleable fittings. They are pretty, strong, businesslike and of admirable shape. In the latter respect they are very superior to our wrought fittings. They tap them with a thread that stands up clear of the body metal, and this thread is tapped taper. It would be difficult to make a bad joint. In addition to ordinary shapes they gave us the 45 degs. branch, the bushing, the eccentric reducing socket, and ditto bushing, the close and open return bend, the male and female elbow and other things. What they have not given us is a guarantee that the fittings shall be water-tight. It is simply distressing.

An English firm has remedied this, and are now making a very high quality malleable fitting which is reliably waterproof always, but, how strange it is ! they have actually copied the two faults that wrought fittings have, and are obliged to have, and they have made the price the same as wrought fittings. The three things making malleable fittings desirable are therefore absent, and it is reasonable to ask what is to be gained by using them compared to wrought ? Simply nothing. Some unnatural people would say this was just like English manufacturers.

Like the radiator, the American boiler has stimulated our manufacturers, for we were sadly behind in getting a large area of heating surface in a moderate compass. A cast iron structure can have corrugated surfaces, heat absorbing pins, complicated flue-ways, and every conceivable means of catching the heat to an extent that is impossible with wrought iron. In the past our boilers were wonderfully plain, and reliance was placed in carrying the flame up and down their sides, which were made as long as possible.

ACADEMY OF ARCHITECTURE AND BUILDING.
1742 Chouteau Ave., St. Louis.
An institute for the technical education of building tradesman and draughtsmen. Students may commence at any time. Graduates are assisted in obtaining positions as draughtsmen, superintendents, foremen, etc. LESSONS BY MAIL, for home instruction. Send 25 cents in stamps for a useful book of interest in self-instruction. Mention the CANADIAN ARCHITECT when writing.
Principal H. MAACK, Architect.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited.
Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

E. COOK, President.	C. P. SHINDLER.
A. E. CARTER, Secretary.	K. M. FRASER.
H. A. BELL, Treasurer.	E. G. HAYNES.
T. BRADBURY.	D. SAUL.

The Fire and Light Committee of the Montreal City Council have recommended that the salary of the City Building Inspector be $1,500 per annum, that an assistant Inspector be appointed at a salary of $1,000 per annum; also an elevator inspector and a wire inspector, each at a salary of $1,000.

It is suggested in Nature that great advantage would accrue from the use of magnetic iron ore as a material for the manufacture of concrete blocks. If magnetite is used instead of ordinary rock broken into fragments, and magnetic sand, or ilmenite sand instead of ordinary sea sand, concrete blocks can be obtained which have all the strength of the ordinary concrete blocks, and which weigh, when immersed in water, twice as much as the ordinary blocks. The great advantage of this additional weight as regards resistance to the waves is obvious.

The Contractors' Liberal Club of Montreal have elected the following officers:—Honorary presidents, Sir Wilfrid Laurier and Hon. S. N. Parent; patrons, Hon. J. I. Tarte, Hon. L. Gouin, and Mr. R. Prefontaine; president, Mr. Elix Sauvageau; vice-president, Mr. J. Grattan; second vice-president, Mr. Jos. Brunet; secretary, Mr. G. T. Gagnon; assisstant secretary, Mr. G. I. Leveile; treasurer, ex-alderman P. Leclaire; committee on rules, Messrs. J. Lamarche, J. Beland, H. Contant, J. B. Brouillette, D. Martineau, Cezairc, Lemay and J. Amesse. Arbitration committee, Messrs. A. C. St. Amour, J. Beland, F. Lemoyne, J. G. Doquette, and P. Lellaire, jr.

THE IMPERIAL VARNISH & COLOR CO LIMITED TORONTO

Fac simile of Brass Cap on each can of Imperial Varnish and Color Co's Architectural Varnishes.

CRYSTALINE

For Interior Use

* * *

THE DELIGHT OF THE DECORATOR

Being remarkably pale in color, it is adapted for fine interiors.

It has a beautiful lustre, and when rubbed makes an exceedingly fine finish.

It can be polished to a piano surface, which it maintains for a very long time.

It works easily, flows freely, and dries quickly.

Toronto Building Department

There are signs of an approaching change in the City Commissioner's office in Toronto, and it would be well to consider the question of changing in a fundamental manner the whole administration of building inspection. At the present stage of the city's growth, and even more in consideration of the growth that is coming on, it is important that the Department should be a Department of Architecture, and that the head of it should be an architect highly trained in modern methods of construction, and able to keep up with new ideas. A permanent official of this character, to amend and keep amended the building by-law, and to carry it out intelligently, would be worth a good salary for he would represent great possibilities for the city. It is essential to have a man who is big enough to be at ease under his responsibilities, or the authority given to him will degenerate into a wretched administration of red tape. But if he is big enough he will do much to foster a good class of building in the city.

The Toronto Exhibition

The Exhibition by-law of Toronto having become law, brings into the region of realities the problem of improving the Fair grounds. The argument for the by-law was that a successful Fair is an advantage to the city, and for this purpose new buildings were required. The main building was not rain proof, and the first consideration, which outweighs all others, is therefore plain and practical—to protect the exhibits; and if the building is made fairly presentable, as the plainest and most practical member of the Exhibition Association will desire it to be, so much will have been accomplished, as compared with the present state of affairs, that the Association may reasonably rest from its labors and say that, as the Exhibition did well before, now, with new and improved buildings, it is safe. But the attractiveness of a Fair from the point of view of beauty, which is already accepted as essential to success, does not depend only upon its buildings. Good buildings and large buildings are essential to give adequate motive for the scene, and an imposing background; but the beauty and the real attractiveness of the Fair lies in the way the buildings are placed and the treatment of the spaces between them. Here is a field for the sort of charm that makes the Fair a sort of recreation ground for visitors, who care little about the exhibits. The possibilities are great and varied, and cost, in comparison with the buildings, little but thought. What can be done to improve the grounds as well as the buildings? To hold its own the Fair must meet the taste that has grown up for this sort of thing. It is not really in a safe position if only the buildings are improved. The difficulty is in the number of fixed conditions that exist. But the alterations that are to be made, and in particular the

condemnation of the main building, open up chances that a good landscape designer might turn to good account; and before the ground plan of the Fair is fixed for another period, by the erection of the new buildings, the block plan should be carefully considered by the architects, if necessary with expert assistance. In all important undertakings in which the treatment of grounds is involved, the best results appear to proceed from a joint committee of architects and a landscape architect.

The O. A. A. Convention

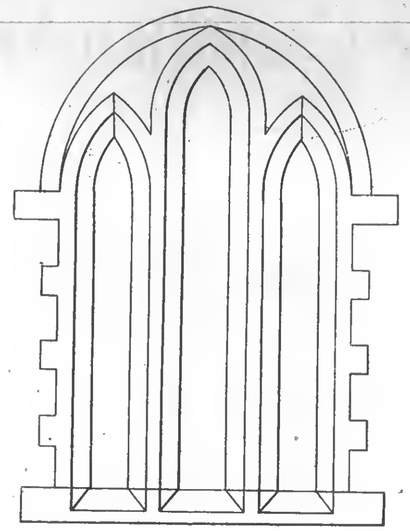
The annual meeting of the Ontario Association of Architects was attended, with three exceptions, entirely by Toronto members. The meeting was entirely harmonious and there were indications of increased sympathy with the educational objects, which were a principal theme of the Convention. The Council and Committees have evidently done a good deal of work during the year in arranging the scheme of subject matter and classes, and in actual tuition. The principal lack appears to be in students. The wedding is ready but they that are bidden appear to be not worthy. It seems a pity that there is no power to compel them to come in. If the special committee of the Legislature, which threw out the bill to make membership of the Association the only way to practise architecture had attended the meeting on Tuesday afternoon, they would perhaps think that an Association which has kept on its educational work without the powers it asked for might well have been entrusted with those powers.

There was no doubt nothing altogether new in the papers of Prof. Capper and Prof. Laird. If there had been we should perhaps have had less cause to praise them. They represented the standard ideas of the present time in their subjects; speaking with authority, as men in a position to know, and in a position which requires them to know, what are not only high but practical aims in these matters. They helped Toronto efforts in the way of confirmation and encouragement from without, and the Association did well in inviting others than members of the Association to come and hear them.

AMERICAN STAINED GLASS.

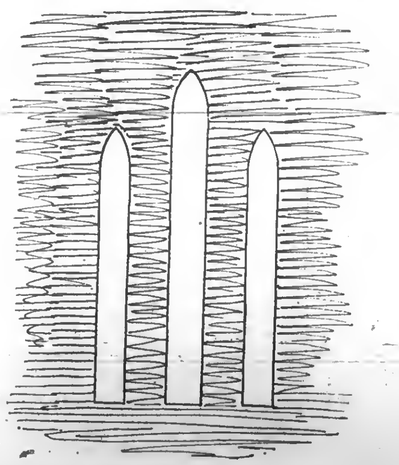
Is American stained glass an improvement to a church? A window has recently been inserted in St. James' Cathedral in Toronto, which raises the question acutely. The disagreeable wall-eyed appearance the opalescent glass gives on the outside is a general objection to the use of American glass, but in the case of St. James' there are particular reasons why, for considerations of inside effect, it should not be used. One of the beauties of this church is the abundant light coming from the aisle windows, which light indeed is a necessity, for the nave seats are dependent upon it.

If the scheme, of which the new north east aisle window is a beginning, is carried out, this characteristic of St. James' will be gone, and we shall have instead an area of gloom provided apparently for the display of a series of illuminated pictures along the sides of the church. The practical discomfort will be intolerable, but it is the artistic loss that is to be most deplored. Any one looking at the church with a seeing eye can even now note the difference between the present effect and a future in the gloom of American glass. The shafting of the columns and the lines of the woodwork are now touched with light from the aisle windows so as to delight the eye. The carving of the cedar organ cases was beautiful under the side light that each received. Now only one is touched with light; the other under the immediate influence of the new window has



lost that charm; indeed the carving is not strong enough to stand the test of dull and diffused lighting.

One can but look forward with regret to the gradual extinction throughout the church of its principal source of beauty. The windows themselves will be among the features which suffer. The glass alone is not the measure of the window. The arch, inside of which the



lancets are grouped, gives the real size of the window, as intended by the designers; and it is essential to the design that there should be light enough to let the relieving arch and its quoined jambs be seen. All this will be upset if American glass is introduced, by the submergence of these details in the general gloom. The windows which it is intended to beautify will

appear unpleasantly narrow, and, the reason for the subordination of the side lancets to that in the centre not being apparent, the grouping will appear to be without reason.

The case is one of conflict between the windows and the church—which is to receive first consideration. The church ought certainly to be the object of consideration, and the first consideration in choosing glass for St. James' Cathedral is that it shall let in light. The only glass that is likely to satisfy the requirement is toned white antique English glass. Figure subjects depending chiefly upon the leading and tones of white, with colour only for emphasis and adornment, would not only shine like jewels in the church and exactly suit its architectural requirements but are eminently suited for sacred subjects. There is something in the pure tints of antique glass, and the necessity for direct purpose in their application, more suited to a religious purpose than the soft and sensuous colours of opalescent glass, and the accidental effects which are a principal object to the makers of American coloured windows. Abundance of colour is in itself no hindrance to religious feeling. The mosaics of St. Mark's are as splendid in colour as they could be made, the robes of Perugino's angels are not only brightly coloured but are lined with another bright colour, and the edges are turned over to show the lining. But in these examples the work is carefully and delicately done to beautify the object to which it is applied. The more pains it receives at their hands the more we receive an impression of serious purpose in its presentation, and the more the subject is exalted. In American work, on the other hand, the subject appears to be but a peg upon which to hang ingenious experiments in accidental effects of colour, procured by manipulating the surface of the glass. The resulting effects—mechanical and accidental—exalt the manufacture but not the subject. The technique is hampering rather than helpful to strong purpose in subject, and, in the American school of glass workers, purpose in subject is not the strong point. The new window of St. James', which represents the descent of the Holy Spirit on the day of Pentecost, seems to be better than usual in this respect, yet it is impossible to avoid feeling that it does not convey the essence of the scene it depicts There is commotion among the Apostles, but it is at something external to themselves. There is not a sign of that possession that required from St. Peter, a little later, the defence that they could not be drunk at that hour of the day. The Apostles have an air of gentle piety, devoutly regarding an apparition of The Dove, which suggests the source of the tongues of fire that are seated upon them. One of them looks round at his neighbor, which it is impossible to conceive of him doing at that moment.

Mr. Harry Simpson, architect, was a candidate for a seat at the Public School Board at the recent municipal elections in Toronto. Although failing of election, his popularity is attested by the fact that he secured upwards of 1700 votes.

The Central League of School Art of Toronto has decided to purchase five large pictures representative of different styles of architecture, together with a collection of other pictures which will be circulated among the public schools of the city.

Branch Office of the CANADIAN ARCHITECT AND BUILDER,
Imperial Building.

MONTREAL, January 17th, 1902.

The building trades in general were perhaps less actively employed than usual last year. Since the great boom of '89 Montreal has not witnessed feverish activity in building. We must take for granted I presume, that a city which has acquired a certain development and has passed the formative period, must count on extraordinary events to create unusual activity. Something like the great Expositions at Chicago or Paris would probably be necessary. As a matter of fact Montreal has but met the wants of the normal expansion of a city of its size since the street widening craze passed, and has not responded to any demands for wild and unnatural expansion.

The year 1901 stands lower in the volume of building operations than many previous years, much lower indeed than the following figures show. In 1889 eighteen hundred permits were granted. Since 1890 a notable decline has been noticeable, 1893 recording one thousand and 1894 five hundred with an aggregate value of $2,750,000; while in 1901 we have 752 permits with an aggregate value of about $2,800,000, being less than any previous year by about 25 per cent. if we remember the weakness of the former reign in the Building Department.

A great many buildings were erected then with total disregard to by-laws add without a permit being taken out, while to-day one has to be taken for a ridiculously small alteration of $30.00 as we have seen this week.

As two or even three inspectors could hardly control all buildings in course of erection in a city of the size of Montreal the new building inspectors upon entering into office established the following system which proved most effective. Every applicant on submitting his plans receives a placard or poster which he is expected to post up in a conspicuous position, together with his permit from the City Surveyor for depositing materials on the street. All policemen on duty report to the head of the district police station any work in progress without the official posters in evidence, which in turn is reported officially by the last named to the building inspector in chief.

We can further explain the steady decrease of building operations on the ground that the city is gradually filling up within its comparatively limited area. People are forced so to speak to seek accomodations in the

suburbs, such as Westmount, St. Henri, Verdun, Notre Dame de Graces, Outremont, Maissoneuve, Delorimer, etc. The proof of this is in the St. Cunegoude, where we could not find to-day three building lots within the limits of that town proper. This state of affairs has existed for four or five years, with the result that as the last census shows that municipality has hardly increased in population for the last decade.

What should be done at the earliest moment possible is the annexation to the city of Montreal of all those municipalities from Longue Point to Cote Saint Paul, which form an uninterrupted agglomeration of buildings and the whole of which is practically one city to us as well as the foreigner who sees no demarcation whatever between these several towns grouped in one of three hundred and forty thousand inhabitants.

The bulk of last year's work was certainly furnished by last winter's big fire in the business district. It is a great satisfaction to find that in most of the buildings rebuilt an effort has been made to render them less inflammable, the Constine Building for instance, immediately behind the ruins of the Board of Trade, being thoroughly fireproof. A Montrealer returning after a two years' absence would certainly not recognize old historic Saint Peter's street; the two sides having been entirely transformed or rebuilt in the lower part.

Several important buildings were erected which deserve more than a passing glance, such as the new addition to the Royal Insurance Company's building, Place D'Armes Square, seven stories high and costing in the neighborhood of $175,000. In connection with this I am glad of this opportunity to give credit to the architects, Hutchison & Wood, for the respect they paid to the architecture of the past (an occurrence so seldom met with nowadays). The individuality of the old building has been preserved by continuing the new portion on exactly the same lines. In a few years the line of junction will disappear altogether by the change of color of the new stone and make the whole an imposing unity.

The Grand Trunk Railway offices on McGill street, by R. A. Waite, of Buffalo, N. Y., costing $500,000; Carsley's new store on St. James street, by A. F. Dunlop; St. John Baptist church and a $250,000 R. C. structure on Rachel street, by J. E. Vauier; the Merchants' Bank building, additional stories, by Edward Maxwell; the Wilson residence, corner of Sherbrooke and Drummond streets, also by R. A. Waite; and the two princely residences on Drummond street, one in the style of an English manor house, for Mr. R. Reford, of the well-known steamship agency, and the other in the fashionable New York roccoco style, for Mr. Chas. R. Hosmer, of the C. P. R. Telegraph Co., by the Messrs. Maxwell, are among the most important works of the year.

But, unquestionably, the building which has attracted the most interest, is the extension to the Bank of Montreal, now being built on Craig street, at a cost of nearly a million dollars. The structure, which is about 150 feet long, faces also on its long side on Fortification Lane, its axis being exactly in the center of the the present building, extending from St. James street to Fortification Lane. As the slope of the ground is quite considerable from front to rear, (the ground floor on St. James street a few steps higher than the sidewalk), it will necessitate the construction of a bridge over Fortification Lane, uniting the two buildings, the older of which will serve as a vestibule; and a monumental one it will be, with its magnificent facade, unrivalled by any other financial institution.

The slope is such that between the main floor level on St. James street and the level of the sidewalk on Craig street, two stories are gained, which will be devoted to public safety-vaults, the main floor being entirely reserved for the banking room, 40 feet high, with no windows, the light coming from the top. To give an idea of the richness of this structure it will suffice to say that no plastered walls will be in evidence, every inch of wall space being marble, and that the 32 columns of 34 feet in height, supporting the lantern, will each cost the sum of two thousand eight hundred and some odd dollars. The shaft will be in exotic marble and the capital in cast bronze, as in the antique pagan temple of old Rome.

This again is a lost opportunity for our architects, as it has been thought fit, as in the case of many of our prominent modern buildings, to call upon foreign architects to design the structure, Messrs. McKim, Mead & White, of New York, being in this instance the fortunate firm.

The erection of the Foley apartment-houses, on Dominion Square, Metcalfe and St. Catherine streets, by Messrs. Saxe & Archibald, acceuluates a new departure in our mode of living started by the Sherbrooke apartment-house. This structure, which is pleasing in appearance, will cost in the neighborhood of $400,000.

What this year may have in reserve is hard to foretell, but from present appearances, notwithstanding what real estate agents may say, we do not anticipate a season of great activity.

It is true, there are a few other mammoth structures to be commenced in the spring, such as the Liverpool, London & Globe Insurance Co. building, corner St. James and Place D'Armes Square. The building, which will comprise seven or eight stories, was thrown open to competition among a few city architects. Afterwards, it is reported, these architects were advised not to complete their designs, as the work had been given to the makers of the conditions of competition, Messrs. Peabody & Stearns, of Boston.

The Birks Jewelry Store, on Phillips Square, will be enlarged by a considerable addition, Messrs. Hutchison & Wood being the architects.

The Guardian Assurance Company has bought the remainder of the Barron Block ground, adjoining the Lancashire Insurance Company's building, designed by Edward Maxwell, and will build an advertising structure, which, it is hoped, for the profession's sake, will not go out of a Montreal architect's office, in order to give the public an occasion once more to compare results with the American building to be commenced at the same date on Place D'Armes and St. James street.

MONTREAL BUILDERS' EXCHANGE.

The Montreal Builders' Exchange have decided to adopt the system which has prevailed among American Exchanges, of renting desk room to supply firms and allow them to display samples of their materials in cases, the object being to make a permanent exhibit of building materials within the Exchange, and at the same time to increase the revenue.

MONTREAL MASTER PLUMBERS' ASSOCIATION.

The Association held its annual meeting a fortnight ago, when the following officers were elected: Hon. president, John Date; president, Thomas Moll; first vice-president, Thomas O'Connell; second vice-president, Joseph Thibault; third vice-president, W. G. Graham; secretary, J. A. Gordon; financial secretary, J. C. Brunet; treasurer, Captain Giroux; English corresponding secretary, J. W. Hughes; French corresponding secretary, Ald. Jos. Lamarche; chairmen of committees: Sanitary, P.C. Ogilvie; Audit, J.A. Watson; Apprenticeship, P. J. Carroll.

ONTARIO ASSOCIATION OF ARCHITECTS

PROCEEDINGS OF THE ANNUAL CONVENTION HELD IN THE ROOMS OF THE ASSOCIATION, 94 KING STREET WEST, TORONTO, JANUARY 14TH AND 15TH, 1902

THE proceedings were opened at 2 p.m., Tuesday, January 14th, 1902.

The following members signed the register of attendance:

Grant Helliwell, H. E. Moore, Edmund Burke, Geo. R. Harper, W. L. Symons, A. R. Denison, J. Wilson Gray, A. H. Gregg, M. B. Aylsworth, W. R. Strickland, F. F. Saunders, W. Percy Over, C. H. C. Wright, John Gemmell, A. Frank Wickson, Wm. R. Gregg, C. J. Gibson, John A. Pearson, Almond E. Paull, R. J. Edwards, S. H. Townsend, Geo. W. Gouinlock, John Kay, Paris, M. Hall, H. C. McBride, London, Andrew Bell, Almonte, C. H. Bishop, W. A. Langton, and the following visitors: G. S. Lemasnie, Eng., C. H. Mortimer, A. H. Harkness, Alfred Baker. H. F. Duck.

The minutes of the last annual meeting were read and confirmed.

The President, Mr. Helliwell, then read his address:

PRESIDENT'S ADDRESS.

To the Ontario Association of Architects in Convention Assembled.

GENTLEMEN,—The Council having elected me to the office of President I have the very great honor and privilege of addressing you in that capacity on this, the 14th annual meeting of the Association.

The year just closed has been a most prosperous one. Throughout the Province of Ontario and indeed the whole Dominion much commercial activity has prevailed. The national resources of our country have been developed as never before, all branches of trade have been busily employed, art and science have kept pace with the general progress, and our own profession has naturally shared in the widespread prosperity.

Under these happy conditions I can greet you with most hearty congratulations. The convention in which you are now assembled promises to be one of special interest and benefit. The committee who have had the task of providing and arranging the programme for this gathering have, as you will see by a glance at the Agenda, accomplished their work with signal success. Those gentlemen who, in response to the committee's invitation, have so kindly consented to come here and address this convention, deserve and will receive, I am sure, a cordial welcome. The names are those of old friends and new and are all deservedly distinguished in their special spheres. Dr. Bryce and Professor Wright have on former occasions read papers of great value and interest, and we can therefore anticipate with much pleasure the addresses they are to favor us with. The accomplished professor of architecture in McGill University, Montreal, is well known to the profession throughout Canada. On a former occasion Professor Capper was expected to address the architects of Ontario, but through some unavoidable cause was prevented. This is consequently the first time we have been favored with the presence of Mr. Capper (who is also an ex-president of the Quebec Association of Architects at our convention.

But this is not all, the Ontario Association of Architects appreciates very highly the honor of having with us at this annual gathering a distinguished representative of the architectural profession in the great republic of the United States. I refer to Professor Warren P. Laird of the University of Pennsylvania, Philadelphia, who has charge of the School of Architecture in that University.

The Agenda informs you of the subjects on which these gentlemen will address the Convention. They are all topics of the utmost interest and value and will, I am sure, be listened to with the greatest pleasure and profit.

In addition to these papers the reports of the treasurer and registrar and of the various committees will be presented. A forestalment of these reports is uncalled for. They will speak for themselves and will, I venture to say, be entirely satisfactory. I cannot, however, refrain from testifying to the faithful and arduous year's work of the committees, and especially, if one might make any distinction, to the work of the Committee on Education.

The curriculums of studies, as prepared by the committees have been printed and sent out to the members of the Association. Two courses have been arranged, a pass course by which students may qualify for registration as members of the Association and an honor course necessitating attendance at the lectures of the School of Practical Science, Toronto.

The honor course is designed to carry the student much farther in technical, scientific and æsthetic training than the pass course. It aims to equip him in the best possible manner for the practice of architecture.

An important feature of the course is that a student may take it concurrently with service in the office of an architect. The committee, after careful study of the schedule of the class work of the School of Practical Science, and by the kind co-operation of the staff there, have so arranged the curriculum that an office student can go through the course by attending the school an average of seven hours during its sessions.

In both Pass and Honor Courses special provision has been made for that most important branch of study, "Design". In this department the student will be trained by means of Studio Classes, conducted on those methods now almost universally adopted in the architectural schools of Europe and America.

A beginning has already been made in this line and Studio Classes are now being conducted on two nights each week in these rooms. The report of the committee having this work in hand will be presented to this Convention and render it unnecessary for further comment on my part.

While dealing with the subject of Architectural Education reference should be made to the work being done in Central Ontario School of Art, in connection with which is a class in Architectural Design, attended by a number of the students of Toronto architects.

Outside of the schools, the profession and the public at large, or at least that portion of it interested in architecture, are receiving valuable education by means of the numerous exhibitions conducted by various architectural organizations in all progressive countries. It augurs well for the future of architecture that wide and increasing interest in such exhibitions is manifested on the part of the public.

The exhibition held in Toronto last winter, under the auspices of the Eighteen Club, enabled the profession and the citizens who attended to form a very comprehensive idea of the progress of architectural design on this continent, and incidentally could not fail to elevate the standard of public taste in matters architectural.

A lecture delivered in Toronto under the same auspices, by an eminent architect of Philadelphia, on the subject of, "The Architectural Adornment of Cities," was also a factor in local architectural education. The keen interest shown in this lecture by our non-professional townspeople was another gratifying proof of the progress of public opinion in these matters.

Looking at the question from a different aspect, the higher standard of architectural taste can be unmistakably seen in the more general recognition of architects as professional men. The progress of legislation with respect to the practice of architecture might be mentioned as one phase of this recognition. The public are rapidly coming to appreciate the necessity for scientific and scholastic acquirements on the part of those who have in their hands the construction of buildings. The restriction of architectural practice to those who have demonstrated their fitness for such responsibility is becoming more general.

Nowhere is this to be seen more than in the neighboring republic, where architectural progress has undoubtedly been more marked and rapid than in any other country in modern times. Some three or four years ago the state of Illinois passed laws for the registration of architects duly qualified. These laws having worked well, several other states have followed the example of Illinois and it is doubtless only a matter of a short time before this action will become general. Even in conservative England, sure, if slow, progress is making in the same direction.

On an occasion like this it is not out of place to take a brief survey of some of the more important examples of recent architectural work. On this side of the Atlantic the buildings of the Pan-American Exposition at Buffalo must first be mentioned. So much, however, has been said and written about these beautiful buildings that it is unnecessary to comment further on their general architectural style. There were those who, in the early stages of the buildings, prophesied that the Exposition would mark an epoch in American architecture, particularly in the external application of color to buildings. In this respect, however, it is now generally conceded that the result was disappointing, not in the application of color but in the lack of it. The brilliant, rich coloring we were led to expect was wanting, the general impression of color being that of quiet neutrality. A few of the domes were conspicuously painted and other parts of some of the buildings were strongly colored, but these were not numerous enough to seriously affect the general architectural scheme.

In England a spirit of electicism seems more prevalent, each architect choosing for himself that style or line towards which he feels most drawn, and along which he pursues his course alone. There are, at the present time, in Great Britain, many architects of high culture and great ability, whose work, chiefly domestic, is delightfully charming. The published illustrations of some of the more important houses, recently erected, show work full of character, inclining to plainness and simplicity of treatment, yet in many respects more satisfactory and pleasing than the immense, magnificent palaces which are building in such numbers in America.

English Architecture fails to show, as yet, any common movement in a specific direction, and it is difficult, not to say impossible, to predict even its near future. The recent discussion as to the style of Architecture to be adopted for the proposed new Liverpool cathedral serves but to confirm this view.

Glancing at recent work in the United States, in general, the influence of the French school is strongly marked, and must have the effect of retarding the growth of a national spirit in American Architecture. At the same time excellent work is being done, better work than any which has preceded it, and the future certainly looks most promising. American architects, if indeed imbued with the spirit of a foreign school, are for the most part working unitedly along the same line, and if the history

of Architecture teaches anything it certainly teaches that its greatest monuments have been the culmination of a long period of earnest, enthusiastic effort on the part of many who labored with a singleness of purpose along one common line.

In our own country Architecture is influenced more by that of our neighbors on the south than by that of the mother land. The climate, the building materials and our general mode of life are all conditions much the same as those obtaining in the northern and eastern states and our architecture naturally resembles their's more closely than that of any other country. Criticism of our work to be of value had better come from an outside, unprejudiced source, and I therefore leave it in other hands. That there is a future of much promise there can be little doubt. The part that our Association shall take in that future depends on its individual members. In the past the Association has certainly accomplished something for the profession of architecture. Judging from the work done during the past year in the line of education alone, it will accomplish more in the future. It has had to bear the brunt of much severe if not unfriendly criticism, criticism the harshest from, in some cases, those who have most fully enjoyed its benefits. Mistakes have doubtless been made, but we believe firmly there is an earnest desire on the part of those who have stood by the ship through many storms, and of those who take the deepest interest in its affairs to profit by such mistakes and to make it a power in Ontario for the advancement of Architecture of which all its members may well be proud. Let every architect throughout the province rally to its support, and such a result will not only be sure but speedy.

Mr Langton read the treasurer's report :

TREASURER'S STATEMENT, JANUARY, 1902.

RECEIPTS.

7 Registration fees	$105.00	
1 Payment on account of registration	5 00	
Members' annual fees, class I	80.00	
" " " " III	33.00	
" " " " V	16.00	
" " " " VI	12.00	
" " " " VII	16.00	
Cheque from Engineers' Club to adjust the balance of common expenses	219.00	
On account of rent of room to chartered accountants	5.00	
Fees for watercolor class	24.00	
Examination papers sold	50	
Interest on bank balance, 1901	29.20	$ 327.89
Bank balance from 1900		1,029.11
		$1,357.00

EXPENDITURE

W. R. Gregg, Registrar	$100.00	
Registrar's petty cash	30.00	
Furnishing rooms	118.30	
Rent	150.00	
Picture framing	21.06	
Convention expenses	40.75	
Design for diploma	12.00	
Engrossing and mailing diplomas	15.00	
Engrossing minutes	10.25	
Publication of Proceedings	22.90	
Stationery	8.75	
Printing	25.34	
Journals	10.00	
Books for the library	10 00	
Gas	2.23	
Insurance	6.43	
Refund of readmission fee overcharged	10.00	
Share of street decorations for reception of Duke of Cornwall and York	7.20	
C. M. Manly Instructor of watercolor class	24.00	$624.21
Balance in hand		732.79
		$1,357.00

In the list of expenditures appear items for furniture, $118.30; pictures, $21.06; books, $10; in all $149.36. It is proper to state this separately as an account of assets acquired during the year, and, from this point of view, to withdraw the amount from the statement of current expenses, thus reducing that total to $472.85. Examining in the same way the treasurer's statement of last year we find a total expenditure of $358, composed of assets acquired in furniture, amounting to $131.89 and a remainder of $226.11, which represents current expenses. It appears, therefore, that our expenses during last year were $246.74 more than the year before. Of this, $150 is rent, an expense incurred for the first time last year. The remainder, $96.74, must be accounted for as the increased cost of living in our new quarters, with an effort to make the Association more useful than before we established ourselves in quarters. Certain items, viz., the cost of issuing a diploma, $27; gas, $2,23; insurance, $6.43; contribution to street decorations, $7.20; journals for our Club room, $10; in all $52.86, are a direct consequence of the institution of these rooms and, as regards the diploma, of our having taken a more decided position in the world. The convention of 1900 cost $3; the last convention, the expense of which is in the present statement, cost $40 75. These items alone amount to $93.61, which is about the difference in expenditure between the two years.

The receipts for fees in the statement of last year were $332.00. This sum included fees paid in between Dec. 30, 1900, when the Treasurer's books closed, and Jan. 29, 1901, the date of the convention. Estimating in the same manner we find that adding $65.00, the amount of fees received by the Registrar since Dec. 30, to the sum of $267.00 which appears in the statement of fees received in 1901, the total receipts in fees from the convention of 1901, to the present, are the same as from the convention of 1900 to that of 1901.

Mr. Burke : In moving the adoption of the report, said: Of course it will be apparent to all the members that our bank account has been seriously depleted by the expenses incurred by the occupation of these rooms, and I think it will be necessary soon to take steps towards increasing the fees or to adopt some means of increasing our income, or we shall not be able to meet expenses.

Mr. Pearson : I think Mr. Burke is right. The difficulty is one that will have to be met sooner or later. We have made an inroad on our capital. This is largely due to the furnishing of the rooms, which we must consider more or less an asset. But there are expenses incurred which cannot be considered in this way and the sooner we face the question of increasing fees the better, as there is no other way by which we can increase our income. What were the expenses before the Association got into the rooms, and what expense are they going to add?

Mr. Langton stated that the expenses in 1900 were $358.00 and the income from fees $332.00. That the rooms having been fairly started, the expenditure should not be quite as high as this in the future, but an expenditure of about $484.00 might be expected.

Mr. Denison : Has the membership fallen off?

Mr. W. R. Gregg : (The Registrar.) The membership is the same. I think the Treasurer's report in the future should include valuation of furniture, library, etc.

Mr. Pearson : Outside of these assets our expenses are increased. Can we not raise the fees?

Mr. Gemmell : Have we got to the point of facing this question yet?

Mr. Pearson : The figures on the board demonstrated that the time for facing this question had arrived.

Mr. Helliwell : I think there is not the slightest doubt but that we are running behind in capital. I think it is the wisest course to face the question now before we get into a critical position. Shall we increase the membership or the fees?

A Member : Both.

Mr. Gibson : There are a large number of architects in Toronto who are not members of the Association. I think that some of these should be members of the Association, and that there must be some reason why they are not.

Mr. Helliwell : The question I think with most architects is, "shall I get what I pay for." If we can make this Association of tangible value to the architects of Toronto they will come in, and pay their fees.

Mr. Denison : Mr. Chairman, it occurs to me that we never have made an actual effort to bring the architects into this Association. We send them printed matter (It is a pretty cold blooded way to invite an architect into the Association). I think a committee should be appointed to meet every individual architect and put the matter before him in a way to induce him to come into the Association. I believe there are architects in Toronto who are desirable men to have in the Association, and that they could be brought into it. It seems to me that architects are a very peculiar people. In olden days one architect would scarcely let another into his office. I am glad to say, since the formation of this Association, architects are not so exclusive, inside the Association, and I think this good-fellowship might be extended outside the Association. Often members let their fees get behind through indifference. If we could only make these members wake up to the fact that to have the world think well of us it is necessary for us to think well of ourselves! If the concern is an active concern members feel that they are getting value for their money; if it is inactive and members are indifferent, everybody treats it in the same way. Continuing Mr. Denison urged that efforts be made in a sincere and active manner to bring new members into the Association, and stated that if it would meet with the approval of the meeting he would like to move that a committee be appointed with this object in view.

Mr. Helliwell : The qualifying examinations which are required by our Act of Incorporation, may be a difficulty in the way of some persons becoming members.

Mr. Wickson pointed out that the Association had made an effort to get in new members at one time, and that a certain number were brought in; also that another effort had been made last year to get in some young men, which was unsuccessful.

Mr. W. R. Gregg : Mr. President, I would second Mr. Denison's motion. It covers a great many men throughout the Province, outside those Mr. Wickson speaks of. There are a great many men outside of the Association who should come into it, and I think a committee should be appointed by the Council to get them into the Association. There are probably 30 or 40 architects practising in the Province who should be members. I have much pleasure in seconding Mr. Denison's motion.

Mr. Helliwell : Mr. Denison's motion is that a committee be appointed to devise means to increase the membership.

Mr. Langton suggested that a committee be appointed composed of Mr. Denison, Mr. Burke, Mr. Pearson and the Registrar, to think over what proceedings they would suggest, to report to the Convention to-morrow, and that then if their report was adopted, the committee should be appointed as a permanent committee, to carry out the proposals of their report.

Mr. W. R. Gregg stated that he had embodied Mr. Langton's motion in Mr. Denison's motion, viz.,—Moved by Mr. Denison, seconded by Mr. Langton that a committee be appointed consisting of Mr. Denison, Mr. Burke, Mr. Pearson and the Registrar to devise means to increase the membership, and to report on Wednesday.

Mr. W. R. Gregg then read the Registrar's report.

REGISTRAR'S REPORT.

COUNCIL MEETINGS—The Council has met eight times since the last annual meeting, and the average attendance has been 5½.

NEW MEMBER OF COUNCIL—Mr. Geo. W. Gouinlock was elected a member by the Council early in the year to fill the vacancy caused by the resignation of Mr. Eden Smith.

MEMBERSHIP—The present membership of the Association is, Honorary members, 3; Resident members, 37; Non-resident members, 26; Total, 66 members.

STUDENTS—The new Pass Course Curriculum for students was issued in April, and copies were sent to all members of the Association.

The Honor Course Curriculum has been printed this month, and is now being sent to members.

Probably on account of the fact that changes were being made in the courses of study, no students presented themselves for examination last March.

Members are reminded that students must serve under indenture such time as is required in the by-laws, and that forms of Articles prepared by the Association, may be obtained from the Registrar, and that a copy of these Articles is required in each case to be sent to the Registrar and filed by him. Also that students are required to give the Registrar one month's notice of presenting themselves for examination.

The by-laws provide that examination shall be held in March of each year.

MONTHLY MEETINGS—On Tuesday evening, January 29th, on the occasion of the last Annual Convention, members of the Association and a number of invited guests assembled to hear a lecture by Mr. G. A. Reid, R. C. A., upon "The Summer Cottage," illustrated by lantern slides, and a description of the Paris Exposition, by Mr. F. S. Baker, F.R.I.B.A., also illustrated by slides.

Monthly meetings were held on the evenings of Feb. 12th, March 12th and April 9th.

Post cards announcing these meetings were sent to each member of the Association. The average attendance was 12.

At these meetings the following matters were considered:—The improvement of the water front of Toronto, the grouping of the Toronto Exposition Buildings, the improvement and better equipment of the School of Practical Science, and the importance of the Government's obtaining the best possible design for the proposed School of Science Building in connection with Toronto University. In connection with these matters correspondence was carried on or interviews were obtained with the Mayor of Toronto, the Exhibition Board, and the members of the Ontario Government, respectively, and the views of the Association were fully expressed and were received, and considered.

The Monthly Meetings Committee takes in hand the securing of papers to be read and other arrangements for the annual meeting, which occurs upon the date set down for January Monthly Meeting.

PROCEEDINGS—The first annual volume of Proceedings of the Association was prepared in February, and four hundred copies were printed. Copies were sent to members and to a number of Canadian, American and English Architects, and others interested in architecture: also to Canadian, British and Foreign Clubs and Societies.

A number of interesting exchanges have been received in return, and these are kept on file in the Library for the use of members, where they may now be seen.

STUDENTS' MEETINGS—The use of the hall on Saturday evenings was granted in April by the Council to the Toronto Architectural Students' Club for meetings of an educational character, and a few of these meetings were held last winter, but the Club has as yet taken no advantage of this privilege during the present winter.

COMMITTEES AND CHAPTER—Important work of the Association has been carried on during the year by the following committees, which have reported progress from time to time to the Council, and have now reports to be presented to this meeting of the Association : Rooms Committee, Mr. John Gemmell, Chairman ; Patrons of Studio Work, Mr. Frank Darling, Chairman ; Educational Committee, Mr. A. Frank Wickson, Chairman ; Revision of By-law Committee, Mr. W. R. Gregg, chairman. The Toronto Chapter, of which Mr. E. Burke is President and Mr. H. E. Moore is Secretary, will also present a report.

The report was adopted.

Mr. Gemmell read the report of the Rooms Committee.

REPORT OF ROOMS COMMITTEE.

Your committee formed to look after the furnishing of these rooms have thought that the evidence of their faithfulness to duty or the reverse is in the nature of things so tangible that a report was hardly required of them. But our Registrar thinks otherwise and has now at the beginning of the third year of our occupation, insisted on a formal report being laid before you.

This we will endeavour to do with the preface that being from private notes, it must not be allowed in its financial aspect to conflict with accounts of the Association duly chequed and paid, but is sufficiently correct to give you the value of the personal property of the Association.

The first item although a most necessary one has cost us nothing —your committee noticing changes in plans as carried out from sketch accepted by Association, by correspondence and interview, persuaded Mr. Horn to install the library cases in lieu of separate entrance and vaults shown on that sketch, and he also stained and varnished floors. Your committee then started house-keeping, Mr. Townsend and myself made repeated visits to the great stores, the only result of which was securing the Japanese rug, an easy chair and curtains for windows and arriving at the conclusion that the stock furniture within our means would give the rooms a hopelessly commonplace effect. We therefore got Mr. Rawlinson to make from sketches, the black oak table and arm chairs in our sitting room which we trust have a more distinctive character.

The fine photo of "Michael Angelo's Moses," was bought at a timely auction sale. The reading desk is a capital given us by Mr Colbrook, to which we added the desk and shaft.

The dog irons were put in by Rice Lewis & Son. The plaster statuary was a donation from W. J. Hynes except the Diana given to us by Mr. Baker as New York's idea of that chaste goddess.

The photograph of the bronze gates of Baptistry at Pisa is a gift from Mr. Langton.

The rooms we would report have been a great convenience for the meetings of Council and committees, and from their central position give us a standing in the community by which we can further the interests we have at heart.

The Toronto Guild of Civic Art asked and were allowed to hold their annual meetings in lecture room, your committee judging their aims are kindred with our own.

Mr Langton and Mr. Darling have given much time and study to students' classes in design, two evenings in the week.

A class in water colour painting has been taught by C. M. Manly on Saturday afternoons and has been appreciated by some members of the Association and students.

We would also report some revenue derived from other societies for hse of rooms on dates not required by either engineers or architects. The Society of Junior Accountants are allowed to hold evening meetings two Mondays in the months of December, January, February and March for which they are to pay $20. $10 was received from Ontario Land Surveyors who held their annual meeting here.

In closing our report we would ask that members be urged individually to make use of the rooms on all possible occasions. If books and periodicals are of value in the pursuit and study of architecture, we have by the kindness of the Public Library and individuals had some of the very best on our table and it is the intention to ask for increase of our periodical fund.

A weekly noon day lunch has been set out every Tuesday by our steward with increasing success and for these we would bespeak a larger patronage—regarding the discussions around the board and after as being valuable in promoting good fellowship among our members, and acquiring a room-frequenting habit, and these meetings have

many times been a means of keeping pace with public affairs that affect architectural progress.

Your obedient servants,

S. H. TOWNSEND
J. A. PEARSON
JOHN GEMMELL
} Committee.

STATEMENT OF PERSONALTY, O. A. A.

½	Assembly room chairs	$ 16 50
	Morris chair	7 55

		$199 41
	Goldie & McCulloch safe	30 00
	Table linen, cutlery and delf	25 00
		$254 41

The report was adopted.

Mr. Denison: Mr. Chairman, I don't see why the City Council should not be waited upon by this Association and asked for help. They make grants to other Associations of like character, and I do not see why they should not make us a grant. They help all kinds of educational institutions, Art schools, etc., and I don't see why they should not help our educational efforts.

Mr. Helliwell: The committee will no doubt take this into consideration.

The report of the Committee on Studio Work was adopted as follows.

REPORT OF THE STUDIO COMMITTEE.

The studio committee consisted of Messrs. Darling, Gemmell, Symons, Langton, Over and Moore. Last winter the studio worked two nights a week for three months. Messrs. Darling, Langton and Over took one night and Messrs. Gemmell, Symons and Moore the other. We gave themes for design presented to the students in various ways and criticised their work with a view to giving them an idea of the fundamental principles of composition. We came to the conclusion that the students are not sufficiently instructed to make this exercise profitable and are devoting ourselves this year to systematic study of the principles of design as exemplified in the historical styles. We are holding classes on only one night in the week as being more convenient for both students and instructors and are proposing to continue them through the whole winter season. Up to the present, Mr. Langton and Mr. Over have been teaching the principles of the composition of the Roman Orders. These lectures are nearly completed and will be followed by instruction by Mr. Symons and Mr. Over in the principles of gothic and of the renaissance by Mr. Gemmell and Mr. Over.

(Signed) FRANK DARLING, Convenor.

Mr. Wickson then read the report of the Education Committee, the adoption of which was moved and carried.

REPORT OF EDUCATIONAL COMMITTEE.

Your committee on Education beg to report that they have arranged two courses of study called respectively "Honor Course" and "Pass Course," each having a curriculum of study and examinations.

The Pass Course has mainly been adopted to suit the requirements of those who are absolutely unable to attend the School of Science, but on the curriculum it is emphatically stated that students are strongly recommended to take the Honor Course.

It is also intended to cover the case of a number, who having already started on their studentship could not well abandon their present position and begin again.

In this course the student is required to serve not less than five years with a principal.

The subjects to be studied and in which examinations will be held, are: Knowledge of Building Trades, Mathematics, History of Architecture, Statics, Strength of Materials, Structural Iron Work, Mouldings, Features and Ornaments, Design, Architectural Jurisprudence, Heating and Ventilation, Sanitary Science, Steel and Iron Construction, and Protection in Buildings.

Students living in any section where studio classes are being conducted are required to attend and graduate from such classes, but all others are required to pass examinations in Design in the final year.

The students are advised to take the Mathematics in Technical Schools where such schools are already, or in the future may be established, the balance of the work having to be taken up individually, but from a complete list of the most carefully selected text-books.

HONOR COURSE.—The Honor Course calls for a higher educational standing on the part of the student before entering.

These students are also required to serve five years with a principal, though graduates from the Ontario School of Practical Science will require to serve three years only, one of which may be served during vacations.

To conform to the opinion held by many architects that a course of scientific training is more beneficial when taken concurrently with office practice, the Honor Course has been arranged to permit the student to take his office and University training at the same time and includes three branches.

"A" Science.
"B" Business.
"C" Design.

The subjects in branch "A" are taught at the S. P. S., the student being required to attend the school about seven hours a week during the school session, and in connection with this a timetable quite feasible in its working has been drawn up showing the hours at which attendance would be required during the five years.

Branch "C" (viz. Design) would be taken up in the Studio work (a separate report of which will be presented) and while no stated examination is held a progression by mentions is necessary for passing in it.

Copies of the Curricula as attached to this report may be obtained from the Registrar.

Your committee feel the members of the Association cannot be too urgently requested to refuse to take pupils except under the conditions that they agree to take in its entirety one of these courses, and if in Toronto it shall be the Honor Course, any other method of service being manifestly unfair to an applicant even if he, in his ignorance of the consequences, be willing to accept a studentship under other terms, and on the other hand equally unfair and damaging to the entire profession.

In addition to the Studio work this season, there has been a water color class conducted by Mr. C. M. Manly, A.R.C.A., which is being attended by some eight members.

A. FRANK WICKSON,
Chairman.

Mr. W. R. Gregg was then called on for the report of the Committee on the Revision of By-Laws. He pointed out several changes in the By-Laws such as the requirement of 5 years practice to qualify for membership of the Council instead of 10 years as formerly; the addition of a Chapter By-law. He said that it was understood that the monthly meetings were not supposed to take powers on themselves that would not be fair to members outside the city who could not attend, but that every member should attend the annual meeting. He referred to the change made in that certain classes of members who formerly paid only $2 a year pay $3 now; so that there are now only two classes of members. Another change relating to fees is, that students coming up for the final examination are expected to pay only one fee covering examination and admission to membership of the Association.

Mr. Burke moved that the balance of business be postponed till after Professor Capper had delivered his address.

Mr. Helliwell: Gentlemen, in introducing to you this afternoon Professor S. H. Capper, of McGill University, Montreal, I bring before you the name of a gentleman well known to you all. The architects of Ontario have for a long time wished to listen to a lecture from Professor Capper, and I can assure him that he will be listened to with the very greatest possible pleasure.

Professor Capper then read his address which was received with hearty applause. (See page 13).

Mr. Helliwell: In presenting a vote of thanks to Professor Capper said he would like to express his personal appreciation of the paper.

Mr. Capper expressed his thanks to the Association and the Chairman for the expression of their appreciation of his address, and regretted that he would not be able to stay over the following day.

The business of the convention was then resumed.

Mr. W. R. Gregg, Chairman of Committee for the Revision of By-laws said that the adoption of the report as far as the convention was concerned was the adoption of clauses 13 and 14. He moved that the by-laws as they had been revised he adopted, seconded by Mr. Moore and carried.

Mr. Moore then read the report of the Toronto Chapter.

REPORT OF THE TORONTO CHAPTER.

The Chapter has at present on the roll of membership 37 resident members.

In submitting this report to the Association it is perhaps necessary to explain that early in the year the Chapter instituted weekly luncheons which have been continued throughout the year with great success. This luncheon is held every Tuesday in the Association rooms and has proved of great benefit, both from a social and professional standpoint, as it has accomplished the desired effect of bringing the members continually into touch with one another.

Discussions have been engaged in on matters of interest to the profession generally. Public questions have been taken up and discussed, with the result that the Chapter has acted directly and indirectly in connection with other organizations on all matters where the public interest is concerned.

Some of the most important subjects taken up by the Chapter during the year are given below.

RE THE ERECTION OF NEW GOVERNMENT BUILDINGS.—After discussion a deputation consisting of Messrs. Helliwell and Langton, was appointed to interview the Government re giving the work to private architects. Mr. Helliwell reported the interview with Messrs. Latchford and Harcourt, and stated there was a strong inclination to employ the Government architect, and that Messrs. Heakes, Wright and Galbraith would be the delegation to visit other cities in the United States for information. It was possible, that a competition would be restricted to Canadian architects, but the work was finally placed in the hands of the Government architect; the Government offering to let the Association look over the plans.

GENERAL IMPROVEMENT OF CITY RE LAYING OUT OF SQUARES, DRIVES, ETC.—The delegation from the Association, Messrs. Burke and Gregg, which attended the meeting of the Guild of Civic Art, reported that a large committee had been appointed to wait on the City Council, urging on them the desirability of employing some competent person to prepare plans for the general improvement of the city. Mr. Langton gave a synopsis of the work of the Guild of Civic Art.

BUILDING BY-LAWS.—Mr. Wickson was appointed to take Mr. Gordon's place on the City By-Law Committee, the latter having to resign, on account of his trip to Corea.

A letter was written to the city urging a conference with the O. A.A., before finally adopting new building by-laws.

TECHNICAL SCHOOL.—A letter was sent to the Technical School board, suggesting that a properly qualified principal be appointed, with special reference to industrial design.

EXHIBITION IMPROVEMENT.—This matter was taken up and discussed by the Chapter, and is fully dealt with in the Association report.

Other matters discussed at the various meetings are as follows: Harbour Square Improvements, Decoration of City for Duke of York's Visit, Dominion Museum. It was announced that Mr. Tarte was in favor of putting the plans for proposed new building out to competition. "Building Permits—What is the Practice of the Architect with regard to giving the Cost of a Building when taking out a Permit?" "The Designation of the Different Floors of Buildings;" after discussion this matter was left for decision at the next convention. "The Yearly depreciation in Value of Buildings."

At the last two meetings, business in connection with the coming convention was discussed.

A very successful innovation at the weekly luncheons, was the exhibition of architectural works and books loaned from different sources for the purpose of inspection by the members.

The average attendance during the year has been, total 407, and it is to be hoped that during the coming year, every member will take advantage of these luncheons, and increase the interest by his attendance.

Mr. Burke: One item of this report was never carried out—the promise of the Minister of Public Works. He promised that we should have the opportunity of criticising the plan of the new building for the School of Practical Science before it was carried out by the Department. We have never had the opportunity of criticising the plans.

Mr. Moore explained that he thought the plans were not far enough advanced yet to criticise them.

Mr. Gemmell: I think this is a privilege the Association should avail themselves of. I think it worth while to remind the Minister of Public Works of this promise.

Mr. A. H. Gregg then read the report of the Library Committee.

REPORT OF THE LIBRARY COMMITTEE.

The library has been well used during the past year, the number of lendings showing a considerable increase over those of 1900.

The Association has subscribed to the regular editions of the Architectural Review, London, the Studio, London, and THE CANADIAN ARCHITECT AND BUILDER, and the current numbers of these periodicals are kept in the rooms for the use of members.

In addition to these magazines the Association receives in exchange for its annual proceedings various weekly, monthly and yearly publications of architectural and engineering societies in Great Britain, France, Italy and United States.

The following new books have been added to the library:—Brigg's "Modern American School Buildings," Carpenter's "Heating and Ventilation of Buildings," Robinson's "Principles of Architectural Composition," and Freitag's "Architectural Engineering."

Members outside the city are reminded that the books of the library will be sent by mail, the postage for delivering the books being paid by the Association. Magazines will also be sent in the same way.

A catalogue of the library is to be found in the Annual Proceedings.

Mr. Gemmell referred to an appropriation which was proposed for getting periodicals.

Mr. Helliwell thought this had better be left to the Committee of Finances.

Mr. Aylsworth read the report of the committee for publishing the proceedings.

REPORT OF PUBLISHING COMMITTEE.

Your committee being still of the opinion that the annual publication of the Proceedings is desirable and in the interests of the Association, recommend that it be continued.

With this probability in view a form and style was adopted that should require no change from year to year except in illustrations and number of pages.

Its distribution in the proper channels by the Registrar has been the means of attracting in return a large number of similar reports from sister associations and other valuable publications always welcomed by the members who avail themselves of the use of the reading room.

The cost of paper and printing was unwittingly borne by Mr. C. H. Mortimer, of THE CANADIAN ARCHITECT AND BUILDER, in accordance with his offer made before learning that the number of copies would be insufficient for an advertising medium, and that so large a proportion of the work had to be set up specially.

As considerable of the matter may be used as set up for THE CANADIAN ARCHITECT AND BUILDER after each convention, thus reducing the cost, and feeling under obligation to Mr. Mortimer, we recommend that for producing Vol. No. 2 his offer at $50 be accepted.

To partly meet this it is hoped that at least one appropriate advertisement may be secured.

With Vol. No. 1 before the convention the committee invite criticism and suggestions for improvement.

Arrangements have been made for reporting this convention in the same manner as that of last year.

M. B. AYLSWORTH,
Chairman.

Mr. Burke: Before that report is adopted it would be well for the Association to notice that it involves the expenditure of $50.00 for the publication. I have had word from Mr. Mortimer, and he states that it is impossible for him to cut that expenditure down, that he cannot get advertisements to renumerate himself, and it cannot possibly be done for less than $50.00.

Mr. Langton said he thought the report could be adopted recommending the publication of Proceedings without adopting the means.

Mr. Aylsworth said that in adopting the report the expenditure of $50.00 would certainly be approved.

Mr. Denison suggested that the report be adopted with the revisal that the Proceedings be published if the Council saw their way to do it.

Mr. Kay was of the opinion that the expense could be met by advertisements in the Proceedings.

Mr. Helliwell pointed out that on account of the smallness of the circulation it was hard to get advertisements.

Mr. Gemmell stated that 400 was the edition, and he thought that a very good circulation.

Mr. W. R. Gregg stated that about 300 had been sent out.

Mr. Gemmell was of the opinion that the Proceedings should be published. He thought it unwise to publish them one year and drop them the next year. He considered that the idea of advertisements was made too little of, that two or three advertisements would meet the whole expense.

Mr. Wright said he thought it most desirable that this year at all events the publication be continued. He considered the money was well spent. While the circulation was very limited, it reached a very desirable class, and he could not see why there should not be in the Proceedings, advertisements of building material, as it reached the very class the manufacturer wished to reach and in the best form. He did not see why there should not be advertisements that would easily cover the expense of $50.00, and he thought it would be a great mistake if the publication was not pushed for another year even at a loss of $50.00.

Mr. Aylsworth said he saw no reason why the report should not be accepted.

Mr. Gemmell thought the motion that should be added to the report was the privilege of allowing advertisements on the cover of the Proceedings.

Mr. Helliwell said that was acceded to, and the report was finally carried.

Business was then adjourned till Wednesday.

SECOND DAY.

Business was resumed on Wednesday, 15th, at 11.55 a. m.

Mr. Denison read the report of the Special Committee appointed on Tuesday:

REPORT OF COMMITTEE ON INCREASING THE MEMBERSHIP.

Your committee recommend that the Council appoint an active committee to see the city members who have allowed their membership to lapse through nonpayment of dues, and architects who have qualified for membership, but who have not yet identified themselves with the Association, to explain to them the advantages and present object of the Association and to request them to renew their membership or enter membership, as the case may be, in accordance with the terms of the by-laws.

Also that a committee of the same purport be sent to out of town members who have permitted their membership to lapse.

Your committee do not see any other practical method of reducing the annual deficit, other than raising the annual dues, or making a special assessment.

Your committee think that each member of the Association could do valuable missionary work in endeavoring to enlarge the membership, and that a sense of individual responsibility regarding the progress and welfare of the Association should be pressed upon every member.

Your committee also recommend that the committee be requested to ask the City Council to make a grant towards the support of the educational work of the Association.

Mr. Pearson: With regard to this question of inducing the other architects in the city to join the Association, I think that we should each one of us make an earnest effort in this direction. It is no good sitting still and listening to this recommendation that the committee should go out and see certain men, but I think that each one of us should make an effort in this way, as we would have a great deal more influence with certain of these than the committee. Each one of us before we leave this room should think of someone he can go and get to join this Association. The outside men should be made aware of the good work that is being done in the Association, of the good papers that are being read at our meetings, of the studio work, etc.

Mr. Kay: Mr. Chairman, if Mr. Denison has moved the adoption of his own report, I would second it. I never see very much good come out of this forming ourselves into a committee of resoluters. It is the individual effort that counts and much more will come out of it. As my friend Mr. Pearson suggests, I think if we would all go out and make an effort much more would be accomplished.

Mr. Denison: I move the adoption of the report. I believe in this missionary work. There is no reason why the members in past years should not have been making this effort, but this is a step in that direction, and I certainly will do my part in connection with it. We have gone through a very difficult stage in our life's history. The Association and Eighteen Club have got apart, but I believe that this thing will come right yet, that we will come together again. There is really good feeling between the Eighteen Club and the Association, but there is some peculiar little feeling between us which I think will die out. I think if we were to unite together we could do wonders in the interests of the young members and of the students, but so long as we are divided, so long as there are two parties, we are divided one against another. If we were together our students would not be divided. It is a common thing for our students to come to us and say, "Where ought I to go: to the Eighteen Club or to the Association?" There is nothing in the way of the Eighteen Club carrying on their own Club, but we should be together; we should be on one plane.

Mr. W. R. Gregg, as a member of the committee, supported the report, and said that he wished to amend his report of yesterday before it was printed. He wished to say that there were 67 members. The Association was not falling behind; it was at least keeping up.

Mr. Gibson: Mr. Chairman, at one time every architect in the province was a member of the Association, now there are not much more than one-third members. There must be some reason why these men dropped out. I think there ought to be some effort to find out the reason of this.

Mr. W. R. Gregg pointed out that the best way to find this out was to go and see these men personally as suggested in the report, as they would be sure to state what they had against the Association.

Mr. A. H. Gregg: Mr. Chairman, Mr. Denison has referred to methods by which the membership might be increased in Toronto, and of missionary work that might be done here. Outside of the city there is also much missionary work that might be done. Mr. Gibson has referred to the reasons why architects have not joined, or have allowed their membership to lapse. I think the reason is often indifference, or is found in the remark, "what good is the Association doing anyway?" Now take "What is the Association doing?" This year the Association has performed a tremendous amount of work in preparing two curriculums of study, the pass course and the honor course, and these two sheets are worth the membership fee to any member. The pass course is arranged so that any student throughout the province who wishes to take up a thorough course of Architecture is enabled to do so by home study. The Association suggests the proper books to read, and is prepared to examine the students. For more ambitious students who wish to take a special course at the School of Science we have the honor course, by which the students can take a course at the School of Science and then go back to their offices to complete their studies, or if Toronto students, they can, by a special arrangement with the government, attend the School of Science and at the same time put in their time in an office. Provision is made throughout the province for a student to take a course that is of advantage to him, and just that one item is worth far more than the fees themselves to every architect who is up-to-date, I should say. And there are other advantages, such as recognition in the law courts, which can be brought before lapsed members, and if it is through indifference that they have allowed their membership to lapse I do not see why they should not be brought back into the fold.

Mr. Helliwell: Along the lines of Mr. A. H. Gregg's remarks, I would like to say that not very long ago I had occasion to advertise for a student, and I was very much surprised to find a large number of young men all over the country who were taking up the course of the Scranton School of Correspondence. But anyone who has looked into the matter will see that the course we have arranged is a considerably better course than can possibly be afforded by this Scranton school, but they do not know it. If there could be any way by which they could know this, and that this course could be carried on at their homes, I think it would in the long run be of great benefit to the Association. We cannot expect to have such influence with the older men to bring them into the Association, but in the younger men is where our help lies. In the meantime I think we may present this report, it is moved by Mr. Denison, seconded by Mr. Kay.

The report was carried.

Dr. P. H. Bryce was then called on for a paper on "The Disposal of Sewage of Houses, Hotels and other Institutions in Towns and Country Places where there is no Sewage System." The paper which was illustrated by charts and figures on the board, was received with hearty applause, and will be printed in a subsequent issue.

Mr. Denison: I would like to ask Dr. Bryce the name of the maker of this valve.

Dr. Bryce: Mr. Quinn, the maker of this valve is here.

Mr. Quinn brought forward a valve of the regular size and in a very explicit manner explained the working of same. The name under which the patent was registered, was the "Quinn Automatic Flushing Valve" and it was manufactured by the James Robertson Co., the cost price being $20.00. He also stated that some of these valves were in use and he had heard of no complaint as yet.

Mr. Burke enquired if this method of sewage disposal included in any form the bacterial disposal of sewage.

Dr. Bryce stated that it included the disposal of the whole of it.

Mr. Burke asked the question if the apparatus described would do away with the grease that would go into it?

Dr. Bryce stated that he had used one in his suburban residence, and the grease was practically all carbonated and done away with.

Mr. Wickson enquired as to the danger of frost affecting the tank, but was assured that if the tank was banked with earth or some leaves thrown over it the frost did not seem to affect it.

Mr. Curry in moving a vote of thanks to Dr. Bryce, mentioned the difficulty of getting enough earth in Muskoka in which to dispose of sewage.

Mr. Wickson: I have much pleasure in seconding Alderman Curry's motion. This subject on which Dr. Bryce has spoken to us to-day is one of considerable interest to us, and we are indebted not only to him, but to this gentleman who has brought this valve down and shown it to us.

The vote of thanks was carried with much applause.

Dr. Bryce in replying to the vote of thanks referred to Mr. Curry's remark about the scarcity of soil in Muskoka. He pointed out that the tank could be build on the rock, and for the final disposal of the sewage an artificial bed of sand could be made to these outlet tanks.

AFTERNOON SESSION.

After lunch Professor C. H. C. Wright read a paper on "The Behavior of Steel under Stress" (see page 16) which was illustrated by charts, scientific apparatus, diagrams and samples, the latter being passed around among the audience for their inspection.

Mr. Helliwell: We have listened to the papers that have been presented, with the greatest pleasure and profit. We have had especial pleasure in listening to professor Capper who came as a visitor to speak to us from Montreal. But it is with peculiar pleasure that I speak of the pleasure we have before us of listening to the gentleman who has come from the neighboring Republic to speak to us. I will not take up time further, but will call upon Professor Laird, and can assure him that coming to Toronto as he does now for the first time he will receive a hearty British welcome. (Clapping.)

Prof. Laird, in taking the platform, stated that he felt not only that he had received a hearty British welcome, but dozens of them since he arrived in Toronto. He then read his address which was heartily received, and which will be printed in a subsequent issue.

Mr. Langton: Mr. Chairman, I may as well take it upon myself at once to move a vote of thanks to Professor Laird for this admirable paper. I hope that it will not close the discussion, but I cannot speak without first speaking of thanks. It is a very full paper, a very complete view of architecture, and one which I am sure we shall be glad to keep in our minutes and look at again when we want to get in our minds the right spirit for carrying out our work. The soundness of Professor Laird's point of view may, I think, be measured by the frequency with which the word "plan" occurs in the earlier part of his paper. In the present welter of styles we can hold to that as the one sure thing. Plan is the basis of excellence, of real excellence, in all styles. It is the touchstone by which to test the quality of our work and to test the permanent value of new ideas. Mr. Langton went on to say that Prof. Laird, in pointing out that the architect of the present day is an organizer and leader of specialists, seemed to indicate that he could not be an inventor in detail. As to the question of style, he had great sympathy with persons who deliberately adopt a style, but he thought the way of true progress depends on the fact that the architect is an artist who does work for somebody else, and the problem presented to him must be at the bottom of his design. As to the handling, one may take an illustration from literature to show that connection between theme and style is natural to a cultivated workman. In the biography of Macaulay, who was par excellence the literary man, at home in literature, we find examples of styles as suitable to their purpose as his historical style, but quite different from it. His drily instructive minutes from India to the home government, his gay letters to his sisters, and impromptu verses, are very different in manner, but all suitable to the occasion—all in fact endowed with style. An artist is essentially a man of his time. His times are reflected in his work. From this we may infer that an architect, so far from abhorring the peculiarities of current local Architecture, ought to find in the reasons for their peculiarity a key to characteristic in his own work. In other words, if a designer is true to his problem he is bound to have Architecture, and if he studies native usage he is bound to have something that can be called style.

Mr. Burke: I have much pleasure in seconding the resolution of thanks to Professor Laird. We had some words of comfort for ourselves in that paper when we were told that costliness was not essential to good style, that sincerity was the best essential of design. We have not the means of putting up costly buildings in Toronto, but we can study with sincerity those that we do put up.

Mr. W. R. Gregg: Mr. President, I wish to support this vote of thanks to Professor Laird, and I wish to say that we regret very much that Professor Laird was unable to be with us yesterday. We had a paper yesterday on "University Training in Architecture." Professor Laird comes from a university that was founded in 1740, Benj. Franklin being one of the founders. The latest addition to that university was the architectural college, and since the year 1890 Professor Laird has been the leading spirit in that college. Central Ontario in the matter of architectural education is just about at the point where he began his work, and I hope Professor Laird will favor us with some words on university education in architecture before he leaves.

The vote of thanks to Professor Laird was then carried by the meeting with much applause.

Professor Laird: Mr. Chairman, during the preparation of my paper I was seized with qualms in the fear that the result of such labors as I put on it would be nothing, and I am not sure now that the paper itself has any distinct virtue or any great value, and it seems to me that the thanks that has been showered on me has outweighed what my paper has deserved. The particular form of architectural education which lies nearest my heart, and nearest Prof. Wright's, has been referred to, and of course I am very glad to speak about that, and I want to speak to you as a colleague of Prof. Wright's, as understanding (while not having had retailed to me) his difficulties, because I know by my own what these must be. Prof. Laird went on to say that the Architectural College of Pennsylvania was one of the latest children of Pennsylvania University, the great distinction of this University of course being having had in its founding the spirit of Benjamin Franklin. He thought perhaps there might have been a similarity of conditions attending the organization of the Architectural School in Philadelphia as compared with that here. There had been no School of Architecture before—a course of architecture had been offered at the University which consisted, however, of scarcely more than the shreds of what might be called an architectural education. Means had not been provided, nor had the Professor of Architecture been given an opportunity of submitting a thorough course of architecture. He then went on to tell how the architects of Philadelphia had conceived the need of an Architectural School in that very great centre of business enterprise and architectural activity, and that the formation and progress of this school was due largely to their efforts. Prof. Laird pointed out that since the thorough establishment of the school the principle that had been

followed was that an architect requires to be a man of a good general education. An architect must be a man with a technical education, but at the same time a man with a liberal education, so that he can take his place among other educated men and give his art the place that it requires. The aim of the University had not been to make the young men merely good draughtsmen so that they could go out and make fine drawings, or to educate them only in any one branch, but had been to give them a thorough training in all the branches of architecture. In conclusion Prof. Laird said that here in the Dominion we probably had not as promising an opportunity for founding an architectural school, but we certainly had the opportunity of securing to our young men the essentials of a good training in architecture. It would require, of course, that Prof. Wright should be aided; he should not be expected, as no one man could possibly do it, to teach all branches of architecture. At Pennsylvania the plan of having the principal branches taught by specialists had been followed up. He also pointed out that the man who is carrying on an architectural school must have the support of all the architects.

ELECTION OF MEMBERS TO COUNCIL.

The names of Messrs. Alexander, Ottawa; Denison, Gemmell, Gray, Siddall, Symons, Wickson, Wright were written on the board, from which three members of Council were to be chosen.

Mr. Helliwell: Gentlemen, our business is to appoint three members of Council. The printed list of nominations you have received has been reduced in number by some of the gentlemen who have declined to stand for the election, and the names of those upon whom you have to vote are on the blackboard.

Mr. Wickson asked to have his name removed from the list.

Mr. W. R. Gregg protested against Mr. Wickson's name being taken off, stating that Mr. Wickson had had a year's rest, had proved himself a very efficient President when he was in, and that the Council needed his presence because he was interested in the work. Continuing he said, "I want to say a little for the unfortunate men, whose names come at the end of the alphabet, and I would like to ask the members to start at the end of the list and select their members." (Laughter). Mr. Wickson thanked Mr. Gregg for what he had said, but stated he did not feel able to fulfill the obligations required of a member of Council, and that was why he wished his name taken off.

Mr. Burke pointed out that one out-of-town member had retired, and wished this borne in mind when selecting new members.

Mr. W. R. Gregg drew attention to the fact that it was necessary to have six men in attendance to carry on the business, that some of the city men were almost sure to be absent, that Mr. Munro, of Hamilton, was on the Council already, and that it would be well to have enough men from the city so that the Council meetings might not be delayed by having to telephone around trying to hunt up enough members to make the required six.

Mr. Saunders and Mr. Kay were then appointed as scrutineers.

Mr. Wright: Mr. President and gentlemen, if I am in order, we have met with a great deal of pleasure during this convention, and I think that we should recognize the fact that it is due very largely to the efforts of our retiring Council, and to our President, Mr. Helliwell, that they have thrown a great deal of personal influence into the preparation for this Convention, and that this is the culmination of a faithful year's work. I think that our retiring Council and our President have certainly fulfilled all the requirements. I think they have, during the year, devoted very successfully a considerable amount of time as well as of energy in promoting and developing that feature of our work which is bound to lead to a successful issue, the educational influence, the educational policy of this Association. And personally I feel greatly indebted to the members of this Council for the personal assistance and inspiration I have received directly through their efforts in bringing to this Association Prof. Capper of McGill University, and Prof. Laird of Pennsylvania University.

It is therefore with a great deal of pleasure that I move that a hearty vote of thanks from this Association be tendered to President Helliwell and to the past year's Council. (Loud clapping.)

Mr. Denison seconded the vote of thanks, which was carried with applause.

Mr. Wickson: I move that a vote of thanks be tendered to the Registrar. As you all know the honorarium which he receives for his work is merely an honorarium for the time and labor that he has put into it.

Mr. Burke: I have great pleasure Mr. Chairman, in seconding that motion. Mr. Gregg has performed an enormous amount of work for the Association.

Mr. Helliwell: The hearty thanks of the Association are due and are hereby tendered to the Registrar. (Applause.)

Mr. Gregg in replying suggested that Mr. Helliwell in presenting the vote of thanks to him was getting out of making a speech himself.

Mr. Helliwell: As far as the efforts of the Council are concerned, I can say the committees have done their work. The committees deserve recognition of the work, and a great deal of work has been done this year. I would just like to say in retiring, that I cannot find words to express my appreciation of the honor which the Association has given me in placing me in this position, and I hope that the Association may go on and prosper more and more as time goes by.

The scrutineers having counted the ballots; Messrs. Wright, Symons, and Denison were found to have the majority of votes.

Messrs. Bishop and Gemmell were reappointed auditors, and the meeting closed.

ELECTION OF OFFICERS.

At a meeting of the Council, held at the close of the convention, the following officers and committees for 1902 were chosen:

President, W. A. Langton, Toronto; First Vice-President, John A. Pearson; Second Vice-President, Geo. W. Gouinlock; Treasurer, W. L. Symons; Registrar, Wm. R. Gregg.

Council—Lawrence Monro, A. H. Gregg, Edmund Burke, C. H. C. Wright and A. R. Denison.

Board of Examiners—Prof. Galbraith, Chairman; C. H. C. Wright, S. G. Curry, R. J. Edwards, W. R. Gregg, Grant Helliwell, Edmund Burke, J. Wilson Gray and S. H. Townsend.

Monthly Meetings Committee—E. Burke, Chairman; John A. Pearson, F. S. Baker and S. H. Townsend.

Rooms Committee—John Gemmell, Chairman; S. H. Townsend.

Library Committee—A. H. Gregg, Chairman; W. A. Langton.

Editing Committee—W. A. Langton, Chairman; F. S. Baker, M. B. Aylsworth, C. H. C. Wright.

Patrons of Studio Work—W. P. Over, Chairman; F. Darling, John Gemmell, W. A. Langton and W. L. Symons.

Educational Committee—Prof. C. H. C. Wright, Chairman; A. H. Gregg, W. L. Symons, S. H. Townsend, A. F. Wickson and A. R. Denison.

City Building Laws Committee—Geo. W. Gouinlock, Chairman; Edmund Burke, A. R. Denison, J. Wilson Gray and J. A. Pearson.

Legislative Committee—W. A. Langton, Chairman; J. A. Pearson, Geo. W. Gouinlock and C. J. Gibson.

R. I. B. A. Examiners—S. H. Townsend and W. A. Langton.

UNIVERSITY TRAINING IN ARCHITECTURE.*

By Prof. S. H. Capper, McGill University, Montreal.

There are various architectural topics that are the subject of perennial discussion, according as one's view leans, with natural bias, to one side or another in matters essentially many-sided.

"Whether architecture is a profession or an art?" is such a topic; upon it discussion—nay, controversy, both bitter and prolonged, has raged interminably; and, in England at any rate, even serious division of council has resulted, with somewhat dissipated energy and hampered action for a time as a natural consequence.

Closely allied is the question of the proper training for an architect during his period of preliminary studentship;—what course will best fit him to do his best? It is a question, I venture to think, of somewhat vital concern to us in Canada. At present, as a people, we are neither very wealthy nor very powerful; we have not yet worked out our scheme of national education at all completely; it is not yet established, as it should be, broad and harmonious, on really national lines; on the contrary, to one coming but newly from Europe, it seems in too many ways seriously provincial in spirit and narrow in result. On the other hand we have across the border-line a great nation for our neighbour, both powerful and wealthy, eager and resolute, and bent, it seems to me, on solving the problem of how to place the maximum of education and special training within reach of all. Those visitors to our meeting who have honoured us by coming from across the border, and whom we all most cordially and gladly welcome here to-day, will not, I am sure, misunderstand me, when I urge the need for our doing our uttermost, in honourable, friendly rivalry, to maintain our own position worthily alongside our greater neighbour and to strengthen our determination not to be out-distanced in that race, the goal of which is national life lived worthily, and the highest development of the intellectual life of all.

In Toronto and in Montreal we have now in Canada two schools for the training of architects. Of the former I naturally do not venture to speak in detail, standing in the presence of many who know it well and can speak with an authority in regard to it that I cannot claim. But I do not doubt that I am right at any rate in this, that in both we are still at the stage of "missionary effort" in our endeavour to promote the thorough training of young architects in the Dominion. Too often our voices are but as those of one crying in the wilderness, where there are none that listen and whence architects do not come forth. In Toronto I do not know exactly how the matter stands at present, but in Montreal, during the five years that I have been at McGill University, encouragement and discouragement have been fairly evenly commingled. Personally, however, I have had the deeply interesting experience of organizing from the beginning and planning out the lines of development for what will, I trust, prove a sound and stimulating school of training in architecture on broad university lines of education.

In so many-sided a field as architecture, which is, it seems to me, an art and a profession, both, and (perhaps) something more besides, there is room for many kinds of activity and many types of mind. To one the solution of problems of construction, with the extraordinary wealth of mechanical resource at the disposal of the modern constructor, is the side of architecture that appeals most strongly; to another, it may be rather the problems of social interest, the housing of the poor, the proper provision for the care of the sick in hospitals, or even the progress of sanitation and the realization of its laws and their requirements; to some it is the nice adjustment of plan and interior arrangement; to others it is the wider field of the composition and design of buildings as a whole and the joy of seeing thoughts take concrete form, as they are realized in actual execution.

It is significant, this many-sidedness of architecture, and justifies in a measure its claim to be at once the broadest of the arts and the foundation of the rest. It brings the architect into touch directly with almost all the other arts, professions and handicrafts, from sculpture and painting to law and medicine and to industries of very many sorts.

And the training for the architect must be broad to correspond, if he is to be adequately fitted for his work. It cannot, of course, prepare him to the extent of endowing him with all the knowledge in all the branches that he may, in the course of his practice, require to master and make use of; that is out of the question; but it should lay the foundation for such acquirement by training the mind to grasp readily the dominant factors in the problems that ask for their solution in well-balanced and harmonious architectural design.

Of the many and varied qualifications that go to make the successful architect in practice, some are of the distinctly practical type, such as business aptitude, faculty of organization and attention to practical detail, while others are as distinctly of the theoretical and academic type; most notably is this true of power in design. Between the two comes construction and engineering, leaning now to the more practical, now to the more academic side, according as it is the more ordinary, rough-and-ready, customary building, or the altogether higher work in calculation and design of the scientific constructional engineer. That this last requires mathematical and scientific training, and is a fitting subject for university instruction, surely needs no argument or proof. The enormous advances made in but recent years in modern steel-construction especially are, I suppose, for the most part the direct result of such scientific study and research. But, if we accept this main rough division into the two sides, the practical and the academic, for the former class let it be at once conceded that the best preparation is the actual stress of daily work at the office desk and the experience that is only to be gained by study at first hand in closest touch with buildings in course of actual execution. Nothing can ever take the place of such practical training, which must always remain an absolutely essential part of the preliminary equipment of an architect. No plea for academic education is ever intended to lose sight of this; nor is it the case that for this practical training academic education is either specially adapted or required. But, while those who urge so strongly that your architect must be "a practical man" are not at all beside the mark, that contention by no means covers the whole of the ground of an architect's education; it does not touch what is after all, if I may be allowed the phrase, the truly architectural side of architecture.

It is doubtless in the ordinary relations of life—though I am not quite sure that I ought to qualify the relations of architect and client as always "ordinary"—a matter of great personal convenience to be on this eminently practical footing, obviating friction and promoting smoothness that may almost be prosaic. Heaven forbid that I should not fully endorse the eminent desirability of being "a practical man."

Even the staunchest advocates of practicality, however, will admit that a great monument of architecture is not to be measured ultimately by the business capacity of its designer, but by some other and higher quality altogether. Jacopo Sansovino is said to have miscalculated the roof for the famous library of St. Mark's at Venice, and to have spent a time in jail as the result. While languishing there he doubtless came to hold a very exalted appreciation of the practical advantages to an architect of being practical; but we, and the many thousand travellers who know nothing, perhaps, of Sansovino's piteous time of incarceration, for whom the library of St. Mark's is one of the buildings that make the Renaissance architecture of Venice so fruitful and delightful a study, are apt to think less of the "practical man" than of the brilliant artist and designer, who has left us so impressive a monument of his genius and skill.

The pre-eminent quality of architecture is in truth design, and this power of design is the vital touchstone of the greatness of an architect. It is in virtue of design and composition that the great buildings of the past, differing utterly, it may be, in point of architectural style, yet, one and all, appeal to us in varying degree. Historical associations may, of course, affect us greatly; other considerations, too, may have to be allowed for in our appreciation; yet architecturally appraised all buildings owe their fame, in chiefest measure, to this power of composition and design. The same is true of our modern work. It stands to reason, therefore, that anything that will foster and quicken power of design must tend to the best equipment of an architect for his life's work.

For design, I venture to claim that academic training is the surest road for most, at any rate, to the achievement of success; that in no other way can the student readily obtain the grasp of the subject, the breadth of view, necessary to attain to the best use of the power that may be his. Design is the expression given to a building; if consistent, convincing and harmonious, the building will have dignity and the incomparable quality of Style. Slip-shod designing will mar any building and make it commonplace and lacking in distinction. With design, then, the architectural student's preparation should begin, and with design it should continue to the end, not (of course) to the exclusion of other necessary studies, but in conjunction with them. Design, it seems to me, should form the basis, the backbone (so to speak), of his course of study from the earliest moment possible, and around it the rest of his subjects should, so far as possible, be grouped. And I base my plea for university training for architects precisely on the ground of the pre-eminent importance of training in design and upon the special facilities a university course affords for carrying out such training consistently in fullest measure.

Nay, I do not hesitate to go still further and to argue that the chief objection usually urged against academic preparation for professional life, the objection, namely, that it is "unpractical," is not in itself a disadvantage in this particular connection. In studying out an architectural design, in developing his ideas so as to bring out of them the best result he can, the student must, at the outset, at any rate, be left as little hampered as possible by fettering limitations, such as economy of cost, restrictions and inconveniences of site, etc. The object of his study is to teach him to think architecturally and to express his thoughts suitably and with grace of diction in the language of his art; to mould them into forms that shall be purposeful and fitting as well as beautiful and gracious.

It is by no means an easy alphabet to learn; like any other language, if I may pursue the metaphor, it takes long to master; it means no short apprenticeship in grammar and expression; for the artistic faculties are slow of development sometimes and always require careful, even toilsome, training. My contention is that for such training no preparation, as a general rule, is more apt or better than that provided by an university course of education. It can offer a well-arranged and systematic scheme of education, such as cannot readily be equalled by any other training. Moreover, it can and does most especially develop the study of design, that being precisely the side of architecture that most lends itself to academic teaching; it thus lays special stress on what, in my view, is the central subject, the foundation of the whole, while it is precisely the subject most difficult of adequate and serious study under ordinary conditions, apart from such a systematic course. It cannot be acquired in ordinary office

* Paper read at the annual meeting of the Ontario Association of Architects, Toronto, January, 1902.

training, where a student, be he never so willing, can at best but "pick up" desultory fragments of the subject. In a busy office each assistant is bound to have his special work allotted to him, without reference to his own requirements as a student; or, if he be a beginner, all around him are too anxious to have him show that he can be of some use to them, to think of his own immediate studies as the matter of first importance to himself. Travel and study are an alternative, but I do not think they are of the most effective service till a student has both learned what to see and how to see it; and both these require the previous training which systematic study of design can best give.

As against this academic instruction, it has been urged that such a course of training will stifle genius—a charge which need not, I think, be very seriously refuted; no sincere education can so fail of its primary object, namely, to "draw out" the faculties and develop them, as to succeed in stifling the superior powers that we call genius—and, secondly, that it will tend to create a dead level of correct mediocrity, dull and wholly lacking the freshness of untrained spontaneity. This, too, appears to me hardly to need refuting. The efforts of untrained spontaneity are not generally, I fear, much more successful in design than in painting or in sculpture; in architecture they too often lead to a wholly unregenerate straining after originality, that appeals successfully neither to reason nor to good taste. And academic training fully justifies itself, if it succeeds in making mediocrity less wayward, controlling its vagaries, and sparing us those frantic abortions in design that remain a lasting instrument—potent for evil—in vitiating public taste.

I would not be thought for a moment to speak slightingly of originality; no gift can be more precious. But originality in architecture is not to be attained through the medium of blatant disregard of accepted forms of architectural expression. It is rather, it seems to me, to be attained more modestly, by absolute sincerity in design, coupled with, or rather dominated by, that rare gift, the imaginative power that naturally expresses itself in form or composition that is beautiful, not ugly. The French use the phrase "voir en beau" or "en laid," to express this faculty, or its opposite. One man will "see," or realize to himself, a design under a form that naturally lends itself to beauty of line or mass or composition; in the hands of another, on the contrary, the same idea will be embodied under forms that are less pleasing, artistically not satisfying. But I cannot think that the former will risk any loss to this admirable faculty, if he seek to educate his powers along the lines I have endeavored to suggest; while the latter may at least have the asperities of diction modified by familiarity with established and well accepted forms.

Perhaps few great architects have shown more striking originality in design than Sir Christopher Wren, in the wonderful series of churches with which he enriched London during nearly half a century after the great fire of 1666. Of them all the great cathedral of St. Paul's is assuredly his master-piece, I suppose the most beautiful and imposing church that the Protestant faith has raised. Yet, in its final form, it is a triumph of academic discipline over daring, but not successful, amateurish spontaneity. Those of you who are familiar with the design as originally approved—in King Charles I's warrant, it is declared to be "very artificial, proper, and useful"—will recall the really grotesque design for the central dome. "A nightmare conception," it has been called, "of two domes and a telescope steeple". It is even surpassed in grotesque extravagance by an earlier scheme of Wren's for the reconstruction of Old St. Paul's, in which a dome was to be "surmounted by a huge open-work pine-apple, 68 feet high, of monstrous and horrible design". Yet the dome of St. Paul's, as actually erected, is one of the most beautiful in existence, its most conspicuous characteristic being, as has well been said, "its magnificent sanity."

The reason for this astounding aberration of England's greatest architect is, probably, simply the lack of academic training. Wren entered upon the practice of architecture as an amateur, and, genius though he was, he never wholly overcame this lack of preparation for his great career; in St. Paul's itself, for which the long series of London churches was Wren's very wonderful preliminary study-ground, there are still minor blemishes in spite of years of patient study—it is idle to deny them—that seem only the result of this want of training in classical design.

Originality does not then, I take it, imply departure from traditional forms in architecture so much as honest, unaffected and gracious use of them in sincere application to the requirements of modern building. Hence it is said that I do not give my adhesion to these who would try to cut themselves adrift from the architecture of past times in order to be "modern." Not from ignorance, but from full and critical knowledge of the past can we create a tradition for the present.

It is idle to seek to evoke a "modern style" in the sense in which "Gothic" or "French Renaissance" were styles at different periods of French architectural history, when builders—both designers and workmen—were all familiar with certain current forms and methods and were restricted to these alone. With our immensely fuller knowledge, we cannot be so restricted, if we would. We can express ourselves in many ways in solution of the same problem, whereas in earlier times one, current, way only of expression was known and, therefore, consistently practiced. And modern architecture gains in this immensely fuller vocabulary, so to speak, if wisely, not extravagantly, used.

The historical study of architecture consequently forms the natural basis for architectural design. Only by knowing the best that has been done can we do the best that can be done to-day. Study of architecture in the past should not, if rightly guided, lead to mere archæological copying or repetition in our work to-day; but it should, if its lessons are properly learned and its teaching taken truly as our inspiration, bring home to us the best that the past has done and set before us an ideal that will serve us as both a standard and stimulus to solve our modern problems as honestly and well. Only out of full and loyal knowledge of past tradition can we to-day hope to achieve in our work results that will be as true and as expressive of our modern life.

In the course in architecture which I have had the privilege of planning out and developing at McGill University, I have sought to give effect to this conception. The full curriculum embraces four years, of which the first is preliminary, devoted chiefly to Mathematics, Physical Science and Drawing, with the very useful addition of practical instruction in the workshops, designed to impart some knowledge of the nature of materials of construction, to familiarize the student with the more important tools, and to give him some manual skill in their use. Only in the second year is the more special work in the different departments of architecture and engineering begun with us.

I need not dwell upon all of the work in detail; I apologize for intruding myself upon you in this direct way. I desire only to emphasize the main conception that has guided me in the organization of the architectural course.

In the first of the three remaining years the teaching is chiefly devoted to a rapid survey of architectural history from ancient Egyptian to modern times, touching successively upon the great eras of European civilization and tracing the evolution of architectural styles in their constructional forms and methods.

The student is thus placed in touch, so far as may be, with the broad lines of his subject, and the present is linked with the past in continuous development. This, it seems to me, should have an important influence on the student's attitude; for, fascinating though the archæological side of architecture may be, it is not as archæology but as architecture that the modern student should regard it.

In conjunction with these historical lectures, a course on the elements of effect in architecture and the main principles underlying the two great divisions of architectural style, the classic and the gothic, naturally, I think, arises; for want of a better name I have called it Elements of Architecture. And from the first, so soon as the student has acquired a little familiarity with the more obvious means of architectural expression, such as the Classical Orders, (which remain, I think, the best primer, so to speak, the most reasonable and effective introduction to architectural form), he is set to express himself in elementary design of plan and building.

In the next year the historical course is devoted to a study in detail of the architecture of the Renaissance down to modern times, in amplification of the earlier general course, while both third and fourth year students take together the more special courses. These comprise detailed study of ecclesiastical, domestic and public architecture, the lectures still dealing with the historic evolution of architectural styles and with the problems and requirements of modern work. A course is also given upon general art history, so as to place the architectural student in touch not only with the decorative details of the different styles of architecture, but also with contemporary forms in other branches of art, especially the decorative arts employed in building.

I have only mentioned the subjects bearing on design, as the central theme round which, in my opinion, architectural study can best be developed in an university course. I have perhaps spoken at too great length already of the work of my own department at McGill University; if so, I again apologize. But I have said scarcely anything of that other side of architecture, construction, for which the scientific training of an university course offers very direct and effective preparation. For modern construction in its more recent progress touches engineering in its completeness of calculation and in its accuracy of design. And again let me guard against the charge of disregarding the practical training needed.

In an university course it is not possible, nor is it attempted, to supersede that side of training for professional practice which is only fully to be gained by practical employment in office and on works. This, the more business side of professional work, must always be learned in actual employment under the conditions obtaining in everyday life. And such practical knowledge of the work before him should, whenever possible, be acquired by the student concurrently with the higher training the university offers, by seeking, during his free months, employment in connection with works in operation or in progress of execution.

This training is manifestly of the greatest importance for the complete equipment of the student. But, necessary as this practical training is, an university course can and does provide for something more, for a thorough grounding in the principles upon which professional practice is ultimately based, an education which can hardly ever be otherwise at all adequately acquired but which, though too often lacking, is essential for attaining the best and highest work in architecture. In design and composition—the key note of the art of architecture—success depends for the most part on the due training of the critical aesthetic faculties; and for such training the education offered in an university course is very directly and specially adapted; for most, the surest; for many, the only road.

I have limited this paper to the consideration of but one side of academic education; I have had but time to mention the other, the training on the mathematical and engineering side which is so important a factor in the modern very wonderful development of constructional engineering; the consideration of this, of course, should have, to do it justice, separate treatment at hands more competent than mine; nor have I ventured into the wider domain of the consideration of general university education, and its power to develop and broaden on harmonious lines the intellectual gifts and sympathies, and to quicken the mental life and strengthen its fibre. All that is beyond the scope of such a paper as mine to-day, which has already detained you, perhaps, too long.

Let me conclude, having thus in a sentence suggested these wider bearings of my subject, with a quotation from one of Oxford's greatest sons which sums this up in words far more eloquent than mine: "A university training is the great but ordinary means to a great but ordinary end; it aims at raising the intellectual tone of society, at cultivating the public mind, at purifying the national taste, at supplying true principles to popular enthusiasm and fixed aims to popular aspiration, at giving enlargement and sobriety to the ideas of the age, at facilitating the exercise of political power and refining the intercourse of private life." Is there any one of these great ends that should not be also the gaol of our profession, the aspiration of us all as architects?

Mr. Gouinlock: I am sure we have all listened with a great deal of pleasure to the instructive paper given us by Professor Capper of McGill University. I heartily approve of the wisdom of the Association in inviting Professor Capper to give us a paper, which I am sure will stimulate the student and the profession at large. I have much pleasure in moving a vote of thanks to Professor Capper for his very able paper.

The motion was seconded by Mr. Denison and carried.

Principal Hutton, of the University of Toronto, who was in the audience, after expressing the pleasure of the outsiders who had come to listen to Professor Capper's address said: Professor Capper said that he would not refer to the advantages that Toronto University offers for the study of architecture because we all knew them so well, but I should like to tell Professor Capper that one of the advantages for the study of architecture is unique. As Mr. Blake said many years ago "the government put up the University Building to show the public how to build, and in case the public would not then know to build, they later put up the School of Practical Science to show the public how not to build. (Laughter.) Speaking as an outsider again, I cannot help feeling that the practical side of architecture occasionally needs some little consideration. I have heard my friends tell of an architect who requiring to put a register into a bed room could not find any place where it could be put but under the bed. (Laughter.) I have also heard it said that the Society of Architects would not be perfect until they had thrown their doors open to women. I am really a little surprised not to see any here to-day, (cries of "O no," laughter.) I know there are a large number of ladies who are very anxious to show how they can build, and I am sure that women would see that plenty of pantries were put in a house, and that a window would not be put in where it would be impossible to get at it.

Professor Capper: Had the architect who built a house with a bed room in it in which you could not place a bed, an academic training?

Principal Hutton: I believe this particular architect had not an academic training. Those who suffered from his ministrations would probably be strong supporters of Professor Capper's views; but I am inclined to think that the part of Professor Capper's paper which would interest them most would be the account of Sansovino's misadventure. They would look back with regret to a time when, if an architect proved incapable, the municipal authorities were able and willing—to clap him into jail. (Laughter.)

Mr. Wright: Mr. chairman and gentlemen, I for one would like to add the expression of my appreciation of the paper which we have just heard from Professor Capper. He has covered the ground very completely, classifying the work of the student under satisfactory heads. The paper deals principally with the questions of design and scientific construction as they should be taught in our universities, while leaving the practical application to be studied by work in an office. If Professor Capper will glance through the course as laid out by this Association, he will see that we have taken very much the same view of the subject as he has. Our Association during the past year has done a good work in organizing this course, and it will do a much better work if it succeeds in carrying it out. The difficulty which we have had in forwarding the purpose of this Association throughout the province is that in the matter of the study of professional work the young men have been beginning in the wrong way. The mistake I think is in the admission of students to professional work; they have in the past been admitted too early in life and at too low a stage in their education. It has been the effort of the Association to raise that standard and it is to be hoped that their efforts will meet with success. The difficulty as far as the younger member is concerned is not so apparent to him at the time of registration, but it becomes more apparent when he comes to practice, and in the matter of guidance in this respect we have in the past not done our duty—if we have failed to require from our applicants a rigid fulfilment of the conditions necessary to qualify as students of the Association.

Mr. Hynes: (visiting member of 18 Club). It seems a unanimous opinion that a university education is desirable for an architectural student, and the question is, how are we to get the students to take advantage of this course. I think perhaps in Mr. Wickson's report there is something that is antagonizing the idea of the University course. That is the apprenticeship system. It is very hard to tie a man to two things. I think that persons who have a little money they wish to dispose of might establish two or three scholarships for the students to strive for in the University, which I think might induce students to take this course.

Mr. Symons: I should like to say a few words with reference to our educational committee. I think Professor Capper said that after all it was the design that gained distinction for an architect, and we give comparatively little credit to the man who has constructed the building in comparison to that given the man who has designed it. I think that we all agree that the men who have reached the highest stage in architecture have reached their height by their distinction in design. My own feeling has been for years that efficiency in design can only be obtained by academic training, by being thoroughly trained for that work, learning the A, B, C of the Orders and so on till we learn to design truly and well. Some people have asked me, what would you recommend to a young man as a course of training in architecture? Now-a-days we certainly make the answer that we can recommend a university training. And though it is sometimes hard for some of us to say whether it is the best, yet the longer I live I am the more ready to say it is the best, and I do not think we are dealing fairly with those who come asking admission to our offices in taking them in. We must be very careful that we are not sacrificing their interests simply to gratify our own pockets, to get them to do our work. Those of us who have gone through what we have, and in whose younger days there was not the chance of these days, must confess that our lacking is wholly I might say on account of our not having had the chances of academic training. (Applause).

Mr. Burke: Mr. President, I have great pleasure in adding my word of testimony as to our appreciation of the paper we have had from Professor Capper. Mr. Symons has touched on the difficult point with reference to architectural education, in Ontario at any rate—the tendency of students to enter an office without or before taking a proper architectural course in the School of Science. That tendency or custom can only be remedied by the architects refusing to take students who have not taken this course. The portion of our work to which Mr. Hynes referred in Mr. Wickson's report, is simply a method of getting over the difficulty with men who are now students; we feel that they should have some advantages, and it is for their benefit that arrangements have been made whereby they may have about seven hours per week at the School for lectures

on the scientific courses in connection with the Association curriculum.

Mr. Langton: Professor Capper's paper has the evangelistic quality which is most valuable in a lecture or paper. One cannot, in the short time that can be occupied by a paper, do much definite teaching, but one can stir up a spirit that will forward the end in view in delivering the paper; and this I think Professor Capper has done. There few of us I fancy who have reached, or are approaching middle age, who do not at this moment regret that the present advantages for students did not exist in our time and that we must be content with being—architects like Wren. (Laughter). The first necessity for architecture now-a-days is training. In the old days architecture was a craft. The architectural conception was common property; and to carry it out in individual cases, all the designer required was to know the grammar of its detail. The case is different now. The number of different works comprised requires a scientific training and the architectural problem is an open one, to be solved only by a mind cultivated to flexibility by exercise in the fields of thought of all generations of architects. Nothing can accomplish this training but long, continuous and practical study. That is the reason for the stand the Association takes. That is the reason for the apprenticeship system. One learns to play the flute by playing the flute. Students don't know that so much education is necessary and that so long a practical training is necessary. They see people set up as architects without it and they think they can do the same. But we know it, and it is our duty to students to lead them, not perhaps as they want to go, but as they ought to go. We have improved our curriculum and our methods. We have taken in good part all the advice the Eighteen Club, as representing youth and modern thought, gave us. We have rooms and facilities. We only want students. We have not got the students we ought to have and I am afraid in some cases they are being kept from us. I think this ought not to be the case. The architect, of whom Professor Hutton spoke, who put a bed over a register and windows in out-of-the-way places, was not an architect in the true sense of the term—in so far as he did these things. I think also that the case of Sansovino's roof is exceptional. It is a commonplace among architects that the architect who is an artist is also a good constructor. An architect is not a mere designer of exterior appearance. In my own mind I separate the word designer from the word architect. Architect is an inclusive term. The architect conceives the building as a whole. The plan is at the bottom of everything and a plan is not a plan that is not conceived of as a thing to be built. The best architect is the best builder.

THE BEHAVOIR OF STEEL UNDER STRESS.*

By Prof. C. H. C. Wright, School of Practical Science, Toronto.

While discussing with one of the members of the Council of this Association the results of certain experimental work of the post-graduate year at the School of Practical Science I was induced to promise a paper on the behavior of steel under stress and in its preparation I have kept in view the younger members and students of the Association.

Inasmuch as the use of steel has completely revolutionized methods of construction and plan, its effect should be and is apparent in the design, nut however, to the extent the material deserves. It has been the custom for years to use rolled shapes, rivets, and joints of an engineering type partly because this branch of the work has been generally relegated to the engineer, and partly because most of the steel work is hidden. Is not much of it hidden because it is considered unsightly? Why should not the parts exposed to view be æsthetically treated and the shapes receive architectural attention.

It has always been considered necessary to study carefully the properties of other building materials. The successful treatment of granite shows boldness or vigor; marble, delicacy or refinement; sandstone, elaboration; terra-cotta, repetition, etc.

While steel has been used very largely during the last decade it will be used much more extensively in the immediate future. It becomes desirable that the members of our profession should, and imperative that the younger members shall, observe closely the peculiar properties and behavior of this important material in order that it may be treated satisfactorily in design as well as in construction. It ought not and cannot be left to the engineer.

Another difficulty that might be mentioned is the action of fire on steel. Serious as this difficulty is from the point of view of design, it must be met frankly and not forgotten that this very same property enables it to be rolled and worked into shapes economically.

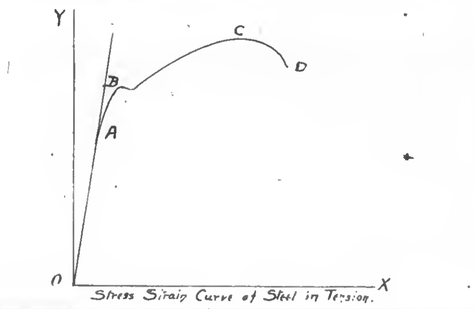
Interesting as this line of thought is, we must turn our attention to the more elementary stages and consider a few of the properties of steel.

Suppose a steel rod (usually 24" long) is placed in a testing machine and a load applied so as to produce tension in the rod. Now if measurements of the lengths of a part of the rod (usually 8") are made it will be found that for every load applied or stress there is a corresponding change in length, a deformation or strain. Further, that when the load is removed the rod will regain its original length.

There is a point however beyond which this is not true, or where the deformation or strain is not constant for equal increments of load or stress. Below this point steel is elastic, while beyond it is plastic. The point at which this change occurs is called the elastic limit. If however a piece of steel be stretched (strained) beyond the elastic limit, and the load removed, it will contract more or less but will not regain its original length.

The measurements of deformation or strain, which must be accurate to the nearest 1-10,000 of an inch, are made with an extensometer of which this Riehle Yale represents a very satisfactory type. As will readily be seen, the points of the screws which fasten it to the specimen are held rigidly 8" apart. After fastening it to the specimen, the bar connecting the two heads is removed, and the two micrometers read or set at zero (the contact being determined by the ringing of an electric bell on the closing of the circuit by the contact). A load is next applied to the specimen, and the micrometers again read, the difference between the two sets of readings, giving the deformation or strain corresponding to the load or stress. If the stress be doubled the micrometers will show that the strain has been doubled. As the stress is increased it will be found that equal increments of load will produce equal strains so long as the steel remains elastic, or in other words within the elastic limit.

If these measurements were continued and the resultant stress strain curve drawn, plotting the loads as vertical ordinates, and the strains as horizontal abscissa, it would resemble O A B C of the accompanying figure.



Stress Strain Curve of Steel in Tension.

In the complete curve there are four significant points, viz., the true elastic limit, A; the apparent elastic limit, B; the ultimate strength, C; and the breaking point, D. From O to A the ratio of stress or strain or load to deformation is constant and the curve becomes a straight line. Between A and B the ratio of strain to stress increases slightly, while at B a very marked change takes place, hence the term "apparent elastic limit." Micrometer measurements of the length are not necessary to determine this point, and consequently it is widely used in commerce, and is often spoken of as "the commercial elastic limit," or often merely "elastic limit." Beyond the elastic limit the material continues to increase in length as additional loads are added until it reaches its ultimate strength, when it begins to fail. It no longer continues to support the load, but stretches under a decreasing load and finally separates under a greatly reduced one such as is indicated in our diagram by the point D.

Specimen No. 1 is a mild steel made by the open hearth process and gave the following results when tested in tension. The length of the specimen was 24 inches and its diameter 1".015. Punch marks one inch apart were made along the rod. The specimen was then placed in the testing machine and subjected to tension. The load was gradually applied and the material elongated uniformly for a time until it reached a point where it stretched under a constant load of 21,000 pounds, i. e. the commercial elastic limit of 21,000 ÷ (1.015x3.14159) i. e. 21,000 divided by the cross section of the rod or 27,200 pounds per square inch. The rod finally broke under a load of 37,700 pounds or of 37,700 ÷ (1.015x3.14159) or 47,200 pounds per square inch of its original cross-sectional area. On measuring the distance between two of the punch marks originally 8" apart (4 on each side of the break), it was found to be 11.08" long; i. e. the steel had an elongation in 8" of 38.5%. Collecting we have :—

Commercial elastic limit .... 27,200 pds. per sq. in.
Ultimate strength ..... 47,200 " "
Elongation in 8 inches 38.5%

The following measurements made on this specimen will show perhaps more clearly the elasticity of the material.

Load in Pds.	Stress in Pounds per sq. inch.	Extensometer readings.	Deformation of Strain.
1,000	1237	8.0005	0.0005
2,000	2474	8.0009	.0004
3,000	3711	8.00125	.00035
4,000	4948	8.00160	.00035
5,000	6185	8.00195	.00035
6,000	7422	8.00225	.0003
7,000	8659	8.0026	.00035
8,000	9896	8.00295	.00035
9,000	11133	8.00325	.0003
10,000	12370	8 00355	.0003
11,000	13607	8.0039	.00035
12,000	14844	8 00425	.00035
13,000	16081	8.00455	.0003
14,000	17318	8.0049	.0003
15.000	18555	8.0052	.00035
16,000	19792	8.00555	.0003

On drawing this stress strain curve, plotting the stresses as vertical ordinates and the strains or deformations as horizontal abscissae we get the following diagram.

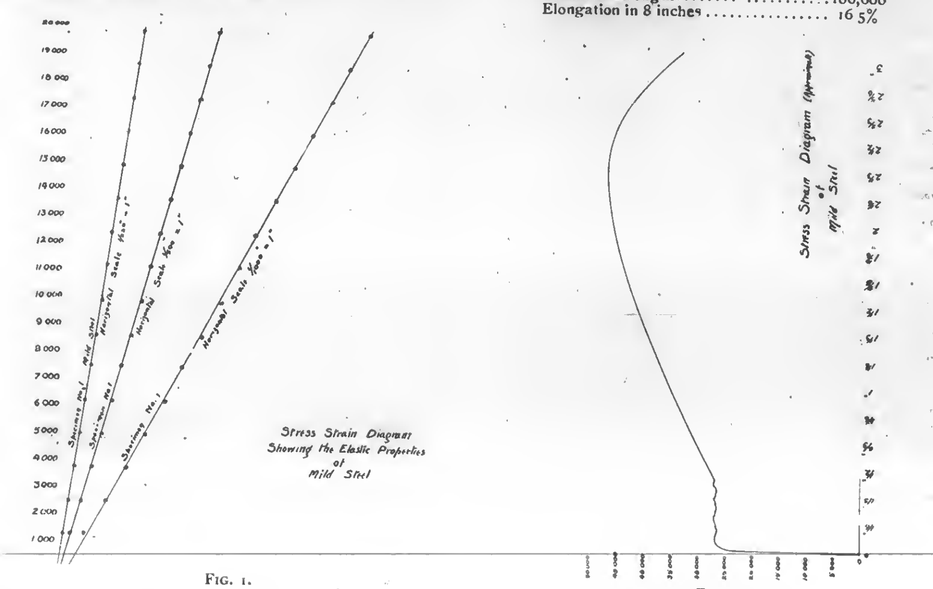


Fig. 1.

The complete stress strain curve is given in Fig. 2.

Specimen No. 2 of Milo Steel, made by the open hearth process, gave the following results in tension:—

Length of specimen, ... 24 inches.
Diameter of specimen, ... 1.015 inches.
Apparent Elastic Limit, ... 27000 pounds per square inch.
Ultimate strength ..... 47500 pounds per square inch.
Elongation in 8 inches, ... 38.0 %

Load,	Stress in Pounds per Square Inch.	Extensometer Readings	Elongation.
0	0	.27135	
1000	1237	.27185	.0005
2000	2474	.27235	.0010
3000	3711	.27265	.0013
4000	4948	.27290	.00155

Figure 3 is the stress strain diagram of specimens Nos. 2, 3 and 4 within the elastic limit. Allowing for reasonable errors of observation the line joining the plotted points is a straight line showing conclusively that steel is within these limits perfectly elastic.

Before looking at the classification of steel let us examine very briefly its composition and process of manufacture.

Cast iron as you will remember is a combination of from 2 to 6

*Paper read at the annual meeting of the Ontario Association of Architects, Toronto, January, 1902.

per cent. of carbon with iron. The large amount of carbon determines its characteristic features or behavior. Wrought iron is the product resulting from the removal of carbon from cast iron. This leaves with the wrought iron such impurities as sulphur and phosphorous. When these are present in too large quantities they render the iron red short or cold short respectively.

Steel is a combination of iron with a percentage of carbon varying from minute quantities to as high as 2%. It is manufactured in the three following ways, viz.—1. By adding carbon to wrought iron—the product of such process being known as crucible steel. 2. By removing carbon from cast iron—the product of this process being known as Bessemer steel. 3. By melting together cast and wrought iron—the product of this process being known as open hearth steel.

Cast iron is hard and brittle and can be moulded, while wrought iron is soft and ductile and can be welded. Steel is unlike wrought iron in that it is fusible, and unlike cast iron it can be forged, and with the exception of high grades it can be welded. In addition to these advantages the higher grades can be hardened and tempered.

The term steel is applied to a class of materials which cover a very wide range of properties. One particular grade may be soft and ductile while another is quite hard and brittle. In tensile strength they may vary from 40,000 to 200,000 pounds per square inch.

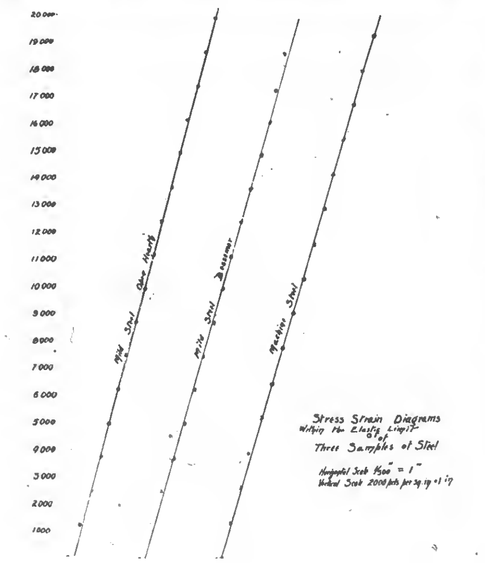

FIG. 3.

It is now customary commercially to classify steels either according to their properties or uses. In the one group there is mild, medium or hard steel, while the other classification includes rivet steel, boiler plate, structural, machine, tool and spring steel, etc.

The following table gives a few of the characteristic physical properties of these different classes:—

Rivet steel should be ductile rather than strong and should have an ultimate strength of 40,000 to 55,000 pounds per square inch; elastic limit, 30,000 to 45,000 pounds per square inch; elongation in 8" = 25 to 35%.

Boiler plate—Ultimate strength 50,000 to 65,000 pounds per square inch; elastic limit, 30,000 to 45,000 pounds per square inch; elongation in 8" = 25 to 30%.

Structural steel—Mild, ultimate strength 40,000 to 55,000 pounds per square inch; elastic limit, 25,000 to 35,000 pounds per square inch; elongation in 8" = 25 to 35%.

Medium—Ultimate strength, 55,000 to 70,000 pounds per square inch; elastic limit, 35,000 to 45,000 pounds per square inch, elongation in 8" = 20 to 25%.

Machine steel—Ultimate strength, 80,000 to 110,000 pounds per square inch; elastic limit, 55,000 to 70,000 pounds per square inch; elongation in 8".

Tool steel and spring steel—Ultimate strength, 120,000 to 200,000 pounds per square inch.

The standard specifications for structural steel proposed by a committee of the American Society of Civil Engineers in 1896 is as follows:

	Lbs. per sq. in.
"Tensile strength low steel	60,000 + 4,000
" " medium	65,000 + 4,000
" " high	70,000 + 4,000

Elastic limit 55% of the ultimate strength of the specimen.

$$\text{Per cent elongation in 8 in.} = \frac{1{,}500{,}000}{\text{Ultimate}}$$

$$\text{Per cent reduction of area} = \frac{2{,}800{,}000}{\text{Ultimate}}$$

Rivet steel when heated to a low cherry-red and quenched in water at 82° Fahr., must bend to close contact without sign of fracture. Specimens of low steel when treated and tested in the same manner must stand bending 180° to a curve whose inner radius is equal to the thickness of the specimen, without sign of fracture. Specimens of medium steel as cut from the bars or plates and without quenching must stand bending 180° to an inner radius of 1½ times the thickness of the specimen, without sign of fracture. While those of high steel also without quenching must stand bending 180° to a radius of twice the thickness of the specimen without sign of fracture."

In connection with the latter part of this specification the following test may be interesting and instructive.

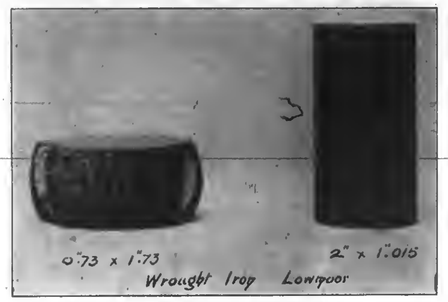
Two specimens, one of mild open hearth and the other of machine steel were heated to a cherry-red, quenched with water and tested with the following results:

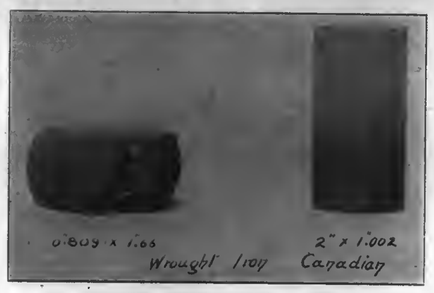
	Ultimate strength pds. per sq. in.	Elastic limit pds. per sq. in	Elongation in. 8"
Mild steel	47,200	27,200	38.5%
Mild steel hardened	62,200	43,000	broke in strips
Machine steel	83,900	55,600	21%
do hardened	106,000	60,500	2%

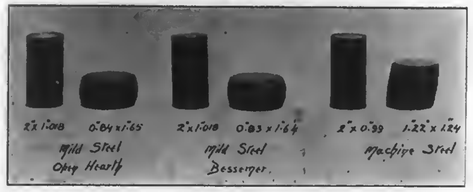
While almost every specification mentions maximum and minimum tensile strengths it is very seldom that mention is ever made of the compressive strength, although the material is used quite as frequently in compression as in tension. This is because the ultimate strength, elastic limit and deformation or strain are more readily determined in tension than in compression, and because the results in tension are the same as those in compression.

Under a uniformly increasing load steel in compression contracts uniformly within the elastic limit, which fortunately is the same as that for tension. When the load increases beyond the elastic limit the material simply spreads and increases the area of its cross-section indefinitely, so that in compression steel has no ultimate strength. This is well illustrated in the following specimens, originally 2 inches long, which were subjected to a load of 170,000 pounds each.

Specimens numberd 1, 2, and 3, are wrought iron, made in Sweden, England and Ontario respectively; while numbers 4, 5 and 6 are mild steel open hearth, mild steel Bessemer, and machine steel. Those specimens which are cracked open or are etched show very clearly the flow of the material under the stress.







The stress strain diagram for steel in compression when the stress is determined by dividing the load by the original cross-sectional area is as indicated in the annexed diagram, FIG. 4.

These compressive tests were made on a Riehle 200,000 pounds machine, and as the screws were kept running at a uniform rate, a set of readings of the times required to produce the stresses were registered on a chronograph simultaneously with the measurements of the deformation or strain. On plotting from these results the stress strain curve and the stress time curve, it is found that they were identical when the scales correspond.

Mr. Pearson: Whilst listening to Mr. Wright's very able paper, I have been brought to look upon the action of stress upon the elements that compose iron and steel in a different light from what I have hitherto regarded it. When such building materials as stone and wood are subjected to stress one can readily understand the action that takes place. In the first instance, when stone is subjected to pressure, the small molecules are disrupted from their setting in the basic cement and the material begins to fracture and crumble away. In the case of wood, the fibres begin to slip past or tear apart from each other. Now, in the case of steel, if I understand Mr. Wright, this action is altogether different. When stress is applied the substance begins to flow. Perhaps I should not say altogether different, but the nature of the substance, as we conceive it is so very different from that of stone or wood, in that it is a more unified or compact mass, that the strain, the resultant of the stress, travels through it, or is transmitted, or flows through it, more in unison with the inherent conditions that are generated by the stress. There is a something in the nature of steel, its elasticity, its plasticity, its resilience, its resistance, its recuperative powers, in that up to a certain point it will again assert itself, or assume its normal condition—that, of all the materials we employ, places it in a class by itself. Now it is because of these integral qualities, that there is a greater unison, a closer affinity between the elements that compose steel and the conditions that arise when strain is present. What is this substance, what is—steel? We seem to know very little about it. We understand it to be composed of innumerable crystals, and these crystals, I suppose, are composed of atoms. Now, imagine a

piece of steel under compression; the atoms or crystals that compose it begin to flow. Are these crystals of such hardness and density that they cannot assume another form and therefore must necessarily move around or upon each other, or do they adapt themselves to the conditions and elongate and compress inherently? What is this adhesive property that binds them together under stress, as the substance itself becomes more compact or elongated? Is it a cement? Is it the attraction of the atoms themselves? It seems to me we want to know more about the composition of steel, its simple elements and their properties, before we can understand the action of strain in the substance. It may be the association of ideas, but when Mr. Wright used the word flow, I immediately thought ot liquids, (Laughter), and I think it would enable us to understand more clearly the action of stress on steel if we could conceive it as a rigid fluid. I would qualify the adjective to the extent of the action of stress upon steel; or, take a bar of soap and we can more readily understand this action of compression or elongation. Mr. Wright has shown us a number of tests with widely differing results, and in some cases by merely hardening the steel, the results vary from twenty-five to fifty per cent. He has carefully led us step by step into such a bewildering maze of tests and figures, and left us there, that I think we feel justified in asking him to tell us what factor of safety we are to employ in the future. (Hear, hear.) In the earlier part of his paper Mr. Wright briefly touched upon the architectural aspect of engineering, wondering if it were not possible for the architect to evolve an aesthetic section of a steel beam or column, exposing them and treating them as part of the design. There are tremendous possibilities in this proposition. Imagine the section of a steel beam in the Queen Anne style, or a Romanesque channel, and then think of it—think of the midnight oil consumed by the engineer in locating the elusive "moment of enertia" or the "radius of gyration" of such fantastic shapes! (Laughter). Until a fire-resisting steel is manufactured, or a steel of something more than the nondescript colour it is at present, a colour that is pleasing and integral, we are justified in painting to get the desired effect, or in covering with such materials as will protect it against fire. (Hear, hear). From the standpoint of economics, in that the shapes that are rolled are universal and are of such contour that they lend themselves readily for assembling, in that the effort is to obtain the greatest strength with the least area of cross-section, or until that day dawneth when we shall view with a sense of exquisite pleasure the lines of a Z bar column, let us "rather bear the ills we have than fly to others we know not of." It is beyond question that the science of engineering has kept pace with the times, manfully meeting and solving the problems that the advancement of civilization unearthed, whilst its kindred profession has been content with the laurels gained in An-

—FOR—

Interior Use.

Designed for fine interiors, and for finishing natural woods.

As water, ammonia fumes, soap suds, heat and dampness have no effect upon it, it is especially adapted for use in bath rooms, laundries, hospitals, public buildings, stables and interior of all kinds of marine vessels where a fine finish is required.

It is very durable, dries quickly, light in color, works easily, covers well and will not crack.

It can be rubbed and will take a high polish.

For sanitary purposes this varnish is unexcelled as it closes thoroughly the pores of the wood against disease germs.

Union League Club House, Chicago

The competition for the Union League Club House is an instance of a successful competition. It was a limited competition for which three well known firms were engaged, the losers to be paid $1000 each. As the proposed cost is $800,000, and the successful architect's fee $40,000, the expense fee, promised to unsuccessful competitors, is a bagatelle to the promoters, and secured them a good competition. If any building is of sufficient importance to make a competition worth while, it is worth while to spend some money in the competition. The conditions of competition are published in the Inland Architect for January, along with the plans. There is no mention of a professional advisor for deciding the merits of the plans. Decision lay with the building committee of the Club. But considering what a city Chicago is for eminent architects and that they are probably all members of the Club, the building committee was most likely an unusual building committee. The competing architects had also an opportunity of appearing before the committee, before the final decision was made, to give a detailed explanation of their plans. This was also a good feature. The result secured is a wonderfully fine plan by Mr. Burnham which seems upon examination to justify without doubt the choice of the committee.

Winter Transplanting of Trees.

An interesting piece of work is being done at St. Louis, in preparation for the World's Fair. The Fair, which is to be placed in Forest Park, where are many large trees, will require the removal of 700 trees; but, both to preserve the trees and to have the advantage of their shade for the Fair, they are to be transplanted so as to line the broad avenues which will remain as a feature of the park when the Fair is over. As the trees are from 12 to 18 inches in diameter, this is an undertaking of more than unusual difficulty, and it will not do to waste time in failure. It is in the method employed to insure success that the interest lies for us. The trees are to be lifted during the winter, while they are dormant and when the ground is frozen so that the earth in which the roots are set may be carried away bodily. There is a suggestion here for another way than the heart-breaking destruction that is sometimes found necessary when a fine tree stands in the wrong place on a building lot. If the transplanting project of the St. Louis Fair is successful, we who have so much more frost—whose trees must be if anything more dormant, or at any rate dormant longer, and who can be sure of removing a greater depth of frozen earth—ought to be able to move a large tree within a lot, or bring to the lot from elsewhere trees that it would take more than twenty years to grow.

The Naming of Floor Plans

A proposition was made at one of the weekly lunches of the Toronto Chapter of the Ontario Association of Architects, recently, that members of the Association should agree to adopt a uniform nomenclature when entitling the floor plans of a building. It was further proposed that the system adopted should be the American system of abandoning the use of the term "ground floor," and calling the floor immediately above the street the first floor. There was some discussion on the reasonableness and simplicity of the American system, but it was

decided that usage alone should settle a question of this kind. It certainly seems as if usage that requires an edict in its favor cannot be called predominant yet. There is reasonableness in the English system too, and a certain descriptiveness which is strong in the mind of anyone who has been accustomed to its use. It is interesting to note that in Mr. Burnham's plan for the Union League Club House, Chicago, the entrance floor is called the ground floor. It is only two steps above the street and is devoted to such uses—the office, telegraph, telephone, coat rooms, lavatories, barber shop, etc.—that it seems proper to call it the ground floor and leave the term "first floor" free for the floor above, which is entirely given up to what the architect calls a "State Suite." Herein is a moral which may often be found in American affairs,—that the most American practice is not always the best American practice; that in the higher developments there is a tendency to return to an old world way of doing things. Let us, who inherit in many things the way of the old world, make quite sure, before we change, that a change is necessary.

Theatre Exits.

The manager of a theatre in Montreal had to appear in court the other day, at the instance of the Inspector of Buildings, because on a single date his programme had not fulfilled the terms of the building by-law, that on every play bill shall be printed a plan of the theatre showing exits and stairways. This is an excellent regulation. It secures an exhibition of the floor plan in a place where it is sure to receive study, along with the jokes and advertisements on the programme which get such careful attention during the waits. To make the regulation fully effective there should be some provision in the by-law for a manner of representation that would invite attention, and a scale of drawing that would be understandable, so as to guard against mere compliance with the letter of the law by the insertion of a half-inch blot that would represent nothing to the inexpert, for whom it is most intended. An incidental advantage of the prominence thus given to exits would be to dispose theatre proprietors more to their consideration. If the law requires a nightly display of the exit qualities of a theatre, it is likely that some pains will be taken that this part of the plan may bear inspection. If, for instance, the plan of the Toronto Opera House were made prominent on the programme it would say in the plainest language that for the sake of space to let in the front of the theatre the lives of visitors to the theatre are nightly endangered, from the way in which the audience from the floor and the balcony are brought to a common exit. The streams from the balcony on each side enter at right angles the stream from the floor. It is true that a balustrade is interposed at the bottom of the balcony stairs to turn the flow from the balconies in the same direction as that from the floor, but it would not stand for a moment a panic rush; and its wreck, thrown down under foot, would insure catastrophe. If the balustrade could stand, the people from the floor might perhaps escape, but what would happen to the people rushing down from the balcony? At the bottom of the stairs from the balcony, which is about six feet wide, they would find a fence, about four feet from the bottom step, obliging them to turn at right angles through a door three feet four inches wide. This is a fine illustration of the feat known as coming out of the small end of the horn. If set down in plan it would look like the section of a sausage machine; and those persons who object to theatres, and hand tracts to people who come out of them, might make use of it to hand to them going in as a graphic representation of the tract entitled, Prepare to meet thy Doom.

Canadian Building Stone.

It is surprising that the abundant building stone of this country is not more widely used. There is plenty of it and in great variety. A valuable paper read before the Ontario Association of Architects by Mr. Andrew Bell, and printed in the CANADIAN ARCHITECT AND BUILDER for March, 1896, ought to have had more effect than it appears to have had in introducing some Ontario stones to notice. Recently the Pan American Exposition has afforded an opportunity which has been to some extent taken advantage of by the Bureau of Mines in making the mineral exhibit of Ontario. The first consideration with the Bureau of Mines was an exhibition of ores but incidentally there was a very fine exhibition of building stone, and the descriptive catalogue of this exhibit should be in the possession of architects who are in the way of using stone. There were eight kinds of granite shown; half from the Lake

MR. W. A. LANGTON,
President, Ontario Association of Architects.

Superior neighborhood and half from that of Lake Ontario. The best specimens were exhibited by the Bureau of Mines itself, showing presumably that there is as yet no commercial development. There was a fine red from Brule Point, L. Superior, and a beautiful grey from Ignace on the C. P. R. in the Rainy River district, where the material is said to be found in immense quantities. The only private exhibitors were T. Sydney Kirby of Ottawa, who showed a sample of grey granite and W. C. Caldwell of Lanark, Ont, who had a dark red. There were twelve examples of Syenite, which looks like granite and often takes its place in ornamental work. The only commercial exhibit was perhaps the most beautiful, a polished block of dark, solid green from Gananoque quarries, sent by T. J. Stewart, Hamilton Granite Works, Hamilton. Sandstone is said in the catalogue to be of common occurrence throughout the eastern and southern parts of the Province. The Credit Valley and Medina sandstones of Messrs Carroll & Beharriell's and Carroll and Vick's quarries are well known. There was also a good red stone of a rather dark colour sent by the Chicago and Vert Island Stone Co., Port Arthur, Ont. Other exhibitors were F. N. Gibbs, Port Arthur; the Cataraqui Quarry Co. Kingston, Ont., and L. O. Armstrong, C. P. R. Offices, Montreal. F. N. Gibbs also sent some cut

blocks of white stone from Thunder Bay. Limestone is said to be abundant in the southern peninsula and the eastern counties. There are quarries at Queenston, Merritton, Beamsville, Wolfe Island, Guelph, Ottawa, Belleville, Huron county and other places. Marble, if one may judge by the number of exhibits, is even more abundant. There were twenty-eight exhibits of marble but most were by the Bureau of Mines. There were all colours—white, black, grey, green and shell pink. There was one piece of statuary marble sculptured; but in most specimens there was some marking. The specimens were said to have been all taken from the surface or near the surface and a more uniform and better quality is promised for deeper development. When will this development take place? The principal beds of marble in Hastings, Leeds, Renfrew and Frontenac counties are not far away from the principal building centres on Lake Ontario; and the Thunder Bay district, which supplied the remainder for this exhibition, is easily accessible by water. It seems safe to predict a market, if wealth continues to grow as it has recently. The use of good material in building will easily become a commercial necessity, and nothing will have a more important influence in developing good architecture.

THE SEWAGE DISPOSAL OF SUBURBAN HOUSES AND PUBLIC INSTITUTIONS.

BY DR. P. H. BRYCE.

It gives me pleasure in complying with your invitation to prepare a paper on some sanitary problem connected with your work, to present a paper on the title indicated, as being of extreme importance, connected as it is, directly with the problem of "Pure Air in Houses," which I discussed before you last year.

As we are well aware, there is a more or less marked difference in the air of country places and of towns and cities, indicated by a small excess of carbonic acid (Co_2) in the latter and the absence of ozone, or oxygen in a nascent condition, due to the excessive presence in towns and cities of organic matters on the surface, in houses, lanes, manure heaps, drains and so on, constantly undergoing decay or reduction to simple compounds by the action of various living organisms, especially bacteria, which utilize oxygen in their biological processes. Sometimes they find this oxygen in the organic compound itself, especially in the azotic or nitrogenous compounds but also in the carbon compounds of a starchy character; in other and under ordinary circumstances, they utilize the oxygen free in the air. As will be supposed, there are different species or classes of this minute form of largely vegetable life, some of which do not thrive in free oxygen and air and some forms what live within the bodies of animals and external to them in free air as well.

To the first class Pasteur long ago gave the name an-aerobes or microbes living apart from air, and the second he called aerobes or those which require free oxygen for their development.

The two classes have properties differing more or less from one other, one especially peculiar to an-aerobes being the liquefying of organic compounds by growing into these and really dissociating their solids, as, for instance, gelatine, forming, of course, by-products during the process both of gaseous and liquid character. The constitution of these chemical compounds varies; that of the gases being principally CO_2, H_2O, H_2S, and many highly organized volatile compounds, such as those given off by the breath of man and animals, those from the many foods and fruits, which develop during their mellowing and decay, and especially the extremely unpleasant emanations given off from putrifying meat, fish and the solid wastes, which pass off to the sewers as excreta, and kitchen and house wastes of every sort. It is a fortunate fact that the products of aerobic decomposition are less disagreeable and injurious than those from an-aerobic decay, since such are those which are most constantly exposed to air from surface decomposition of outside matter everywhere. With these preliminary remarks it will be easy to see something of the nature of the problem to be dealt with in disposing, safely and conveniently, the house wastes which go by the name of sewage, or those matters which are conveyed by water into underground pipes or sewers.

It is the experience of every local health officer, and a source of constant difficulty to the Provincial Board, that in those towns where a sewerage system does not exist and in many houses in the suburbs of towns, even where such systems are, in rural districts and in the large temporary summer resorts, hotels and cottages, the problem of what to do with excretal matters, both animal and vegetable, has been everywhere, if not difficult, yet the most constant one which the local boards have to deal with in the matter of nuisances, and which in many cases proves the most constant danger to the household immediately interested, and where streams or lakes are polluted, not unfrequently has become the occasion of some sudden and serious outbreak of typhoid fever or diarrhoeal disease. The fact that 253 examinations of water were made during the past year at the Provincial Laboratory, most of them due to outbreaks of typhoid, shows that the causal relationship between polluted water and typhoid and diarrhoea is well recognized, and general observation, as well as laboratory work is quite agreed as to the direct connection between such pollution and some accumulation of decomposits of animal or vegetable matter. Privy vaults, deep pits, or cess pools, constant contamination of the area around the house pump with kitchen washings and slops of every kind, hotel stables and barnyards, soakage from slaughter houses, the wastes from cheese factories and creameries and the heaps of refuse from canning factories, and indeed every kind of manufactory in which organic products are used, may become direct means of pollution to wells and sources of public water, and many are moreover the cause of serious injury to health from their creating effluvium nuisances.

Now, perhaps, gentlemen, as it may be only occasionally that as architects you are called upon to deal with more than one of these sources of ill-health, viz., this one of the disposal of house sewage, including excreta, kitchen and chamber wastes, in places where there are no public sewers, it is most essential that some general principles should be laid down and acted upon with a view to the safe, economical and aesthetic method of disposing of such organic wastes.

Probably every one here accepts the theory that in the economy of nature nothing can be lost, or that matter is indestructible, and perhaps all will, in a general way, agree that whatever is yielded by the soil, as, for instance, the potash, phosphates, ammonia and so on, which are contained in the grains and other fruits of the earth, should be given back to Mother Earth for her goodness to us. So in spite of man's foolish waste and ignorance, they ultimately are returned to her, but at an enormous cost of time and energy. Carried to the sea, sewage will form deposits ultimately forming new land, or in solution will become the food of microscopic vegetable forms of many species of the deeper ocean planton and of the larger plants of the ocean littoral, which in turn becomes the food of the microscopic infusoria and finally the food of fishes, molluscs and other sea animals, and so is brought back finally as food to man. Were we intelligent and careful we would see to it that not a single pound of organic waste matter is allowed to decompose out of its place, in other words, to so act as to return to the earth every ounce of C, H, O, and N, which taken from the humus or upper layer of soil is year by year being used up by cultivation and must be returned there, if fertility of the soil is to be maintained.

As however, it is found in practice in most parts of this country that there is a lack of appreciation of the manureal value of such materials, and that the adoption of what is known as the dry-earth system in houses and institutions has not proved free from objections, owing to neglect to supervise it carefully, owing to its cumbersomeness, and as moreover it does not do away with either the need for water pipes and a supply of water being laid on in the better houses, or of the need for disposing of the kitchen and chamber wastes, in any case it is evident that the growing appreciation of modern conveniences in houses is demanding some systematic method for dealing with all house wastes, whether for kitchen or closet by the water-carriage system.

I propose, therefore, to indicate how in practice such a system may be established, at once efficient and economical. In the annual report of the Provincial Board of Health for 1898 a chapter is devoted to "The Biological Principles Involved in the Purification of Sewage," which to those interested will be found to contain a very full discussion of the scientific principles of this whole matter. There will be found a table giving the average analysis of town sewage. While probably less concentrated than the sewage of a single house, since it would contain water from factories, from sub-soil drainage and so on, yet it will very well serve as an illustration of the contents of sewage. It is as follows:

1. Solid matters in suspension—
   - (a) Organic.....20 grains per gallon.
   - (b) Mineral.....10 " "
   - Total.....30 " "
2. Solid matter in solution—
   - (a) Organic.....20 grains per gallon.
   - (b) Mineral.....50 " "
   - Total.....70 " "

Or expressed in parts to 1,000,000 such a sewage would yield:

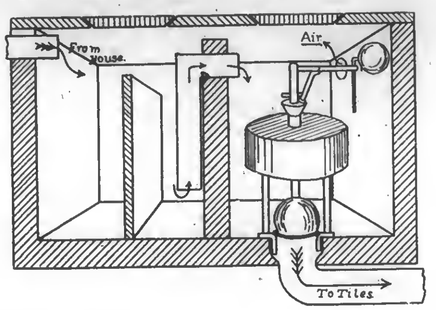
Total Solids.	Solids in Suspension.	Chloridne.	Free Ammonia.	Albumenoid Ammonia.
1428.0 parts	428.0 parts	120.0	50.0 parts	10.0 parts

Assuming what is in experience ample, 20 gallons per head per diem of sewage, it will appear that for an ordinary dwelling with 10 inmates, with a water supply laid on, there will have to be disposed of daily 200 gallons. By reference to the analysis it is clear that half the organic matter, or that in suspension, could easily be removed by any crude filtering method, as by a screen, a grit chamber, or even by passage over coke or some readily destroyed material, should it become clogged.

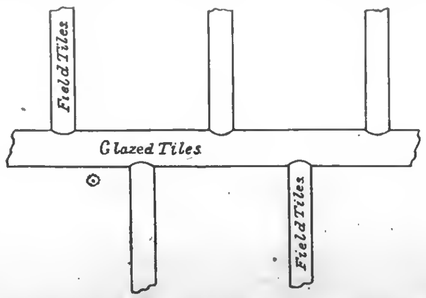
Assuming, however, that all the materials are carried to a common recepacle or tank at the end of the house sewer, there will be deposited daily 8,000 grains of organic matter, whether suspended or in solutions, and 12,000 grains of mineral matter or altogether some 3 lb., of which two-fifths is organic, or is, capable of undergoing decomposition, most of which will gradually be carried away when dissolved in the 200 gallons of water daily passing into the receptacle, the balance of carbon gradually being deposited in the tank. Of the mineral matter 50 parts are

* Paper read at the annual meeting of the Ontario Association of Architects, Toronto, January, 1902

in solution as potash, lime and other salts, which will likewise be carried away in the water. It thus appears that some 100 grains of insoluble mineral matter will deposit in the tank daily with small amounts of carbon, or in 365 days for such a household not more than 10 lbs. of mineral matters will have accumulated. That such is true may readily be proved by anyone caring to make the experiment, as I have done, that such a tank at the end of a year has not had a total deposit of solid matter, greater than can be held by a half-bushel measure. If the balance then, after decomposition, is capable of being carried along with the 200 gallons of water daily, it is clear that nearly all of it is capable, like any other soluble material, of soaking away into the soil with the water, if the conditions are favorable.



I have had drawn up for your inspection the diagram of a tank, which is intended to deal with such materials in a way to give the organic matter an opportunity to decompose, the water carrying the soluble materials, being gradually removed from the decomposing tank, which we may call the septic tank—the word septic meaning putrid or decomposing—to a second tank, whence it may be discharged by a simple apparatus, at such intervals as may be found practical to produce the best results. The question then arises: In what manner can we dispose of this organic matter in solution, conveniently and in such a way as will not create a surface nuisance, or a pollution of ground water? Let us assume that by a series of sub-surface tiles, laid in a proper manner, we can distribute the 200 gallons over an equal number of feet of surface. It is plain that each square foot would receive 1 gallon of water daily. As soils vary in their capacity for water, from a coarse sand which will hold in its interstices not more than 25 per cent. of its volume of water, to a tenacious clay which holds 75 per cent. of its own volume of water, it is apparent that if one gallon of water were poured on the surface of a cubic foot of dry soil, there would not be any water leaking away from the bottom of even a coarse sand, since a cubic foot of water equals 6.25 gallons; so that it requires 1½ gallons to be poured on such foot of dry sand before it begins to drain away from the bottom. A dry clay would hold three times as much before it began to leak. In practice it will be seen that two four-inch tiles, laid side by side, would distribute such water fairly well over the surface of a cubic foot of earth; and also that the water contained in them soaking out of the open joints and pores of the tiles would rapidly dispose of the small amount of water received by each tile daily. In practice it is found that in any ordinary porous sandy soil or sandy loam, tiles filled twice daily will rapidly dispose of the charge of soluble sewage poured into them; and, lifting up tiles after several years' use, I have found them lined



only with a fine stain of black carbon, the volume of the tile not being materially lessened. I have further found that even heavy clay soils with an occasional underdrain have been quite adequate to dispose of the amount of sewage poured into them from an institution of 125 inmates.

It may be proper now to briefly describe the method of construction of such a system of tanks and sub-surface tiles. As in any system of house sewage, it is convenient to arrange all the fixtures so as to discharge into one soil pipe. These being brought out beneath the ground-floor through the foundation, or, if the house be on a hill-side, it may occasionally be possible to bring them out under the cellar floor so that the wash-tubs there may be discharged into them, if this unsanitary plan for the laundry be adopted, the soil-pipe will be led to the top of a tank made of brick and cement in a manner similar to that shown in the diagram. If most convenient, this tank may be built directly against the house to save iron pipe and to prevent its appearance on the lawn, since, as will be seen in a moment, it is necessary that the discharge pipe of the tank on level ground be not more than a foot beneath the surface. The capacity of this tank n the case we are discussing will be such as to hold in each compartment 100 gallons, to be discharged twice daily. It will be seen therefore, that a compartment 2 x 3 x 3 feet will nicely hold 100 gallons, or a tank of interior measurement 4 feet long by 3 wide and and 3 deep is adequate for two compartments each holding 100 gallons.

The arrangement of the interior of the tank is shown in the diagram. As in all sewage tanks, the plan is adopted of having several divisions, the sewage becoming less dense as it passes from one to the other, thereby aiding to make that discharged from the valve chamber as thoroughly liquid as possible.

It will be seen that from compartment No. 1 to No. 2 the fluids are drawn off by an overflow pipe from about midway beneath the surface since at the bottom will be found sediment, while the whole surface is covered with the decomposing matter, which appears to the eye a solid mass, but is really the organic material kept floating by the contained gases of decomposition. The liquids, which pass over of course contain a large amount of organic matter in solution, being composed especially of ammonia (NH^3) and carbonic acid (CO_2) combined as ammonium carbonate with the sulphur compounds as ammonium sulphide. These are held in the second compartment until 100 gallons have accumulated, at which moment the flush valve operates automatically and discharges in a minute or two the contents of the tank into the sub-surface tiles. It is apparent that the size of the tanks may be made such as to deal with 1,000 gallons quite as readily as with a 100.

The sewage thus discharged must, it is evident, be carried to tiles so laid that each tile will get its own share of sewage and no more. It is apparent that with a rapid discharge, the tiles laid on an exact level will each receive this amount, if together they hold exactly 100 gallons, provided the air which is in them be displaced. It is found in practice that in a loose soil the air from tiles laid near the surface readily gives place to the water, if discharged under the head in the tank. Where the soil is level, as of a lawn or garden, it is apparent that the matter is a simple one. If on a slope it is equally apparent that some careful detail work will be necessary in order that the tiles may, at the same time, be kept at the same depth beneath the surface and also receive each its own share of sewage. To complete the description of the tank it is apparent that as some gases, in excess of what are in solution, may be given off into the space over the sewage, it will be necessary to prevent them from accumulating and forcing themselves through the cover of the tank. This is obtained by making the cover of rough boards, and if thought proper, they may again be covered with earth and sod. The gases, if any pass outward, will be absorbed by the soil. In addition to this however, it is necessary to provide for the ventilation of the tank. This is done by a large goose-neck leading from the distal end of the tank, which admits cold fresh air and thus will displace the warm gases of decomposition which are carried up through the soil-pipe to be discharged above the roof as in ordinary house-plumbing in cities where the separate sewerage system is in operation. It may be asked, what ultimately becomes of the organic matter carried away in solution. In reply I would say that through the action of the microbes of the soil the ammonia salts are rapidly nitrified—that is, are changed into nitrates or nitric acid, which at once combines with the lime and potash salts of the soil and thus has become a neutral salt in a condition to act as plant food for the grass or vegetables growing above it.

The following table by W. D. Scott Moncreiff, from the Ashstead experiments, 1895, illustrates the change:—

Effluent from cultivation tank.

Chlorine	Free. N. NH^3	Oxygen consumed	Nitric Nitrogen	Total Oxidized N	Total N of all kinds
9.0	12.5	10.3	9.843	0.12	0.12	12.46
From final filter tray after complete nitrification.					
7.5	0.25	0.2	0.58	9.0	9.0	0.6

As the tank arrangement from which these experiments are taken, was essentially a tank of this kind, except that, instead of the microbes of the earth to do the work Moncreiff had arranged a series of artificial filters or pieces of coke over which the sewage from the septic tank flowed, by which means the liquids for analysis could be obtained, there is nothing different in principle to the system we are discussing.

Little more need be said, I think, to make it clear that in these results of the study of biological processes, which convert organic matter back to its original constituents, we have not only a practical lesson of how to apply science to our every day needs and convenience, but we may also see how economical is Nature and how wholly wise in her operations if she does not have man attempting in his ignorance to violate some of her primary laws. To me it daily seems more true, the more that I try to comprehend the meaning of the processes of Nature in this fine old world of ours.

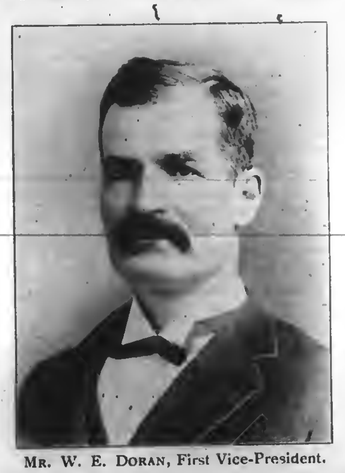
"That nothing walks with aimless feet,
That not one life shall be destroyed,
Or cast as rubbish to the void
When God hath made the pile complete."

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The eleventh annual meeting of the above Association was held in the rooms of the Quebec Section, City Hall, Quebec, on January 23rd, the President, Mr. G. E. Tanguay, in the chair. Those present were

Mr. Joseph Venne, President.

Messrs. G. E. Tanguay, J. E. Larochelle,, Thomas Raymond, E. B. Stavely, J. P. Ouellet. F. X. Berlinguet, Charles Baillairge, W. D. Baillairge, J. P. E. Dussault, R. P. Lemay, H. Staveley, and J. H. Lebon, from Quebec; Jos. Venne, G. A. Monette, J. S. Archibald, Jos. Perrault, D. Brown, J. Z. Resther, Jos. Sayer, Eric Mann, A. Raza, Prof. S.



Mr. W. E. Doran, First Vice-President.

H. Capper, R. Lacroix, Chas. Bernier, M. Perrault, J. E. Huot, A. T. Taylor, Alfred Venne, A. A. Cox, L. A. Amos and Simon Lesage, from Montreal.

The Treasurer's report showed that from the 31st of August, 1900, to 31st December, 1901, the receipts were $2,581.54, which, together with the balance on hand at 30th August of $514.40, totalled the sum of $3,095.94. The expenses were $1,515.54, thus leaving a balance on hand of $1,580.40.

The report which was submitted is a lengthy one and deals with the various subjects of importance to architects in a lucid and effective manner.

In regard to the tariff, the Council accepted an offer by Mr. M. Perrault, M.P.P., to bring the schedule of charges, as accepted by the Association, before the Lieutenant-Governor-in-Council.

Mr. Perrault did not succeed in obtaining the Lieutenant-Governor's assent to this schedule; and, on behalf of the Association, accepted important modifications thereof. As thus modified, the schedule of charges was approved and signed on March 6th, 1901.

During the year legal proceedings were taken against

Mr. R. P. Lemay, Second Vice-President.

eleven individuals, who were practising as architects without being members of the Association. In one case these proceedings are still pending; in every other case a satisfactory settlement was ultimately obtained.

This year the Quebec architects had the opportunity of employing for the benefit of the Association their influence with the members of the Quebec Government, in order to have the tariff made law; and working in conjunction with Mr. M. Perrault, architect and M. P. P., they succeeded.

The Quebec section has this year started the organi-

Mr. J. S. Archibald, Treasurer.

zation of a library of architectural books. The first works bought were those recommended to students for matriculation; said books are in the hands of the secretary at the disposition of the Quebec students.

It has been decided to buy each year a certain number of works on architecture, which will be the property of the Quebec section.

The following officers were elected :

Presiden.—Mr. Joseph Venne, Montreal.
First Vice-President—W. E. Doran, Montreal.
Second Vice-President—R. P. Lemay, Quebec.
Secretary—Prof. S. H. Capper, Montreal.
Treasurer—Mr. J. S. Archibald, Montreal.
Councillors—Mr. C. E. Tanguay, Quebec ; A. Raza,

PROF. S. H. CAPPER, Secretary.

A. C. Hutchison, A A. Cox, D. R. Brown, S. Lesage, Montreal.

DESIGN AS AN ELEMENT OF PRACTICE.*

BY PROFESSOR LAIRD, University of Pennsylvania, Philadelphia, Pa.

Good old Sir John Evelyn, in presenting to the world his "Parallel of the Antient Architecture with the Modern" delivers himself of these thoughts in addressing the reader :

"Before I do altogether resign this *Book* to thy Judgment, I advertise thee, that 'twas not my design in compiling it to teach any man." ***"I expect that men should presently say of me.***That I teach nothing particular and extraordinary here ; that the *Books* from whence I have gather'd all that I say being common and much ampler than mine, there was no need to have scummed them thus superficially over ; That it had been better to have search'd and produc'd something which the World had not yet seen.***But we shall not appeal to such Arbiters as these.****"Poor Men that they are, to believe that in fantastically Designing some one kind of particular *Cornice* or like Member, they are presently the *Inventors* of a new order.***As for those others to whom Nature has been more propitious, who are indu'd with a clearer Imagination, they very well perceive that the true and essential Beauty of *Architecture* consists not simply in the minute separation of every Member *apart* ; but does rather principally result from the *Symmetry* and *Oeconomy* of the *whole* which is the Union and Concourse of them all together, producing as it were a visible Harmony and Content."

Evelyn's ardent contention that the works of the ancients were worthy of the most reverent study and even literal reproduction, and his lofty contempt for those who ignored them and sought unrestrained novelty, showed that the conflict between progress and precedent was in full force on the eve of the great fire of London. And the splendid work that followed that event offers full evidence, not that precedent triumphed, but that the architectural impulse of a people grows with noble vigor into a splendid fruition when planted in a soil of unrest and aspiration, of vital interest in new problems and reverent study of old achievements.

Let me adopt this author's defence as my own. Far be it from my intention to teach or to offer from the book of experience any new thing, for its precepts have been well scanned and its lessons well learned by my audience. Yet even Evelyn's imagined critics would have conceded that the best known truths take a new force when reaffirmed, and I shall therefore venture to ask your attention to some of the more evident principles of our professional work in the hope that they may be acceptably reiterated and profitably discussed.

That Truth is the basis of all that is good in Art is but another way of affirming the breadth of principle upon which our own art is based, for the best architecture has always been an exponent of truth. And the best architecture has always expressed as its highest purpose the aim to build nobly : with the extreme of pleasure to the eye and the mind, with the utmost of stability and with the fullest adaptation of means to the end. All great buildings realize these conditions and are noble because of this fact. The same impulse and motive inspired them, whether the mind that produced them was that of priest or painter, sculptor or scholar, the impulse to build what should be more than mere building, to enrich and decorate in a way that should mean more than ornament alone, to surpass the simple utilitarian demands of the undertaking ; in other words to fuse these elements into a thing greater than their sum, nobler than their aggregate ; the highest aspiration of man's creative power—a perfect building !

In no two periods of Architectural history have the conditions been identical under which architects have worked and until modern times, indeed, the authors of buildings have not been known as architects in the sense in which we use that term. But in all ages and under whatever conditions, great architecture has been in evidence, and it should and can be no less so in this age.

Our situation as architects is unlike any that has preceded our time. We are devoted intensely and exclusively to Architecture as an occupation. We are consciously a class, standing before the world a group of men with a definite purpose and judged by high standards which we have ourselves proclaimed. The commercial and industrial development which has distinguished this age has brought into full flower the organizing of human effort and, with it, the systematizing and subdividing of human labor. Distinctions are sharply drawn between its various lines, and specialization has been forced into all fields. The architect has thus evolved as a necessary factor in modern life, emerging from those ranks which in the past were variously made up either of the scholar who indulged in Architecture as an elegant pastime, the painter or sculptor who regarded it as an allied province ; the engineer, the art craftsman and the studious artizan. Any of these and all have been architects at one time or another but today the architect is none of them. He must combine the offices of artist, constructor and man of business. The range of his responsibilities covers æsthetics, engineering and finance. His obligation to his client, whatever the actual magnitude of his commission, is usually one of greater pecuniary importance than that client entrusts to any other professional man. Upon the soundness of his judgment depends the security of life of multitudes who use his buildings. Of him is required artistic performance of the highest order in the greatest of the fine arts, whose product is always on view, and universal and continuous in its influence. He is successful in his professional career only as he meets the exacting demands of these dissimilar functions, either of which might be regarded as a distinct vocation. It might well be questioned if any human being—much less every member of an entire class—could meet such demands by finding in his person the required mental and temperamental qualities. Unquestionably No! But that architects do successfully meet them is proven in numberless cases, where the requisite mind and temperament are associated in congenial companionship and effective co-operation.

The conditions which have so enlarged and complicated the practice of architecture have also rendered success possible. The commonplace that "we are the heirs of all the ages" is nowhere so true as in our own profession. The lessons and resources of history lie at our fingers' ends and all Europe at our doors. Scientific spirit and industrial development have unearthed and classified one and brought the other. Highly organized systems of technical education are available for our preparation for life work, and to aid in that work the services of specialists of every description abound on every hand. The age is that of the card index with everything in stock, duly labeled, ready at hand for immediate and effective use.

But in all this marvel of development and organization, of the multiplication of resources and the simplifying of labor, one everlasting truth shines with undimmed brilliance. There must be a

* Paper read at the annual meeting of the Ontario Association of Architects, Toronto, January, 1902.

master mind, a single dominating influence, a subordination of all functions to a dominating purpose. Creative work of any kind demands this; particularly is it true in the Fine Arts and notably so in Architecture. And in this the controlling influence must be that of Art,—not science or business enterprise, for if it be either of these the result is barren engineering or mere building for the sake of money-getting.

We must understand Art, however, as meaning vastly more than appears at first view. Broadly speaking it should mean the entire creative side of our work as opposed to the executive. In this sense it comprises all those processes of study or preparation through which the final result is reached and which are supplemented by the actual execution of the work. I do not mean that every part of this study can be regarded as artistic in itself, but that in the performance of every part the controlling motive should always be a desire to contribute toward the perfection of the whole as a work of architecture. We are too prone to think that parts of our work can be divorced and carried on independently—that some parts are non-architectural and hence can be treated in a spirit entirely foreign to that of architecture. No greater mistake could be made, for nothing so much operates against the improvement of the art of building as the notion that architecture is a detachable part of it.

Design proper, in its broadest sense, is the assembling of materials in such a manner as produce structure at once stable, appropriate and beautiful. This means that a well-designed building is one in which the plan is well composed, the resultant building well proportioned and appropriately ornamented, the structural parts well adjusted to the work each is to do and the completed building properly adapted to its uses. To effect a consistent result it is necessary that all phases of the work of design be carried forward in a sympathetic relation. The scope and limitations of each should be recognized in manipulating the others, that none transgress and prevent proper exercise to each in its own field. Let us give some detailed consideration to the several features of Design in this broader sense. Inasmuch as the artist must give initiative to the work, it is proper to look at the question first from the viewpoint of composition or design in its more academic sense. Here we must attack first the broadest aspect of the problem, leaving minor considerations to subsequent study. The general nature of the problem must be studied—the essential purpose of the proposed building, the demands of its occupants and the limitations of its site, cost and materials of construction. Once these salient points are clearly understood, the study of plan must begin by a grouping and arrangement of its greater divisions, a search for the *parti*, for that general disposition which will permit the most direct and simple, economical and convenient grouping of the parts. This is often, perhaps always, the most clearly obvious arrangemeot when once discovered, yet, like other useful inventions, often the most difficult of discovery.

The plan now has attained its general character and this should be regarded as fixed. The major parts of the building are found to be properly proportioned to their uses and have the most convenient relation to each other. The thoroughfare system is logical and ample. Constructional economy has been rendered possible by directness of vertical supports, the delimiting of span, the simplifying of main lines for the mechanical systems. The artistic character of the building, in the praportions of its masses, is assured of a fair prospect of certainty by the mass proportions of the plan. And the further development of the scheme in respect of its practical requirements is assured of success for if the demands of the problem are clearly stated and realized in a broad, simple direct manner in the *parti*, the detailed requirements will fall naturally into place. The plan at this stage is however quite elastic and capable of much minor modification.

During the progress of this study the elevations have been kept generally in mind and the building has assumed a more or less clearly defined general character. These may now become the object of as direct study as has been the plan. The elevations follow close upon the plan in order that they may be governed by and give expression to its fundamental character. But this must be done judiciously with full regard to proportion and scale, relation of parts to each other and the whole, and the effect of line, color and light and shade. For this purpose there must be a certain independence of action ; a freedom from the restraints of a plan whose lines have been too far fixed ; too fully crystallized. This is possible if the treatment of the exterior is preceded only by the determination of the *general* character of the plan. From that point both may well be carried on together, each being adjusted to the other while either is developed to its own natural and reasonable end.

The considerations which should control this phase of the work may be summarized as follows :

First, as to the practical uses of the building.

Distribution : the provision and disposition of the required areas.

Circulation : the development of the thoroughfare system.

Concentration : the grouping of parts, locating of thoroughfares and minimizing of space to effect economy of time and labor to the occupants of the building.

Construction : the simplifying of structural lines to effect economy of construction and installation of mechanical systems.

Second : as to the appearance of the building :—

Proportion : This must reveal itself as clearly in the plan divisions as those of the exterior. For the plan may be made as expressive of the beauties of composition as the elevation. The proportions of the building and of its component parts, as well as the inter relation of these parts, are indeed expressed by the plan in two of their three dimensions and by the elevation in but one, and although the latter completes and perfects the proportions, these may be predetermined and expressed, to a remarkable degree, by plan study. If this element does not exist in the plan it cannot be properly realized in the completed design, for good proportion is inherent in the whole mass of a building, not in any of its superficial aspects.

Expression : If the plan is as carefully studied with a view to proportion as is the exterior, the unity thus given to the whole will contribute toward, if it does not produce that vital quality known as expression—a portrayal of its principal constructive divisions ; the "outward and visible sign" of its inward and actual nature. I do not maintain that this expression should be a rigid and mathematical labeling of the internal subdivisions but that it should not only not contradict the plan but should portray its main groupings and their relative importance and significance in a manner that shall be readily grasped and understood by the observer.

So much for certain of the more theoretical considerations that affect design. Further questions arise which must be answered for each problem out of its own limiting conditions. Among these may be named : Choice of Style, Method of Construction, Nature of Materials and Limitations of Site.

In speaking of Choice of Style I shall not venture upon the troubled waters of that sea of controversy whose name is Precedent. It is a stormy waste, but its currents are well charted and its shores offer to every mariner a haven of refuge to his own liking. And it may be safe to say that if he uses a compass of plain common sense a safe course is reasonably assured to him. But otherwise not. On one hand the purist is in constant danger of misdirection and absurdity, for he will clothe the modern plan with the habiliments of Imperial Rome or of its Italian revival, or mask a frame of vertical pressures with the externals of resistance to lateral thrusts. Archæology is his god and all his buildings bend the knee to it,—for scarcely a joint in their frames escapes some adjustment to the demands of Precedent. But is the freebooter not even more dangerous, with his contempt of all that the purist holds dear, an attitude usually serving as an indifferent cloak to crass ignorance. He glories in his self-styled originality and always finds an audience to applaud its monstrous fruits. It is not difficult to excuse, although we may not approve, the purist, but who can forgive vaunting ignorance and self-confident vulgarity ?

But these extremes are happily as rare as they are extreme, and the search for the golden mean, for that course which shall carry forward into modern practice the lessons taught by the past, is the motive which is near the heart and inspires the best effort of the great body of our practitioners. And under widely different titles it is engaging the attention of the schools and the professional bodies, notably so in recent deliberations of the Architectural League of America.

I confidently affirm that we shall proceed to the solution of this problem as we frankly recognize and freely adopt on the one hand the heritage of the ages, whether it comes through the demonstration of great principles or the use of traditional forms themselves ; and on the other hand as we recognize the demands and limitations of modern conditions, of local environment, of the native building material and, above all,

of the intensely individual and unique nature of the work in hand at the moment.

When, therefore, the question of Choice of Style arises let it be answered on the basis of common sense,—for let us admit that it is bound to arise and must be faced. Let it first be decided which of the historic styles best adapts itself to the method of construction to be used and most happily expresses the purpose or uses of the building. This point is not to be determined by the success with which the pure historic form can be borrowed and applied without change, but through a careful study of its underlying principles, both constructive and æsthetic. If the style is worthy of study, it will be found to have developed consistently throughout; the essential character has grown out of constructive requirements; minor parts take form and proportion as a secondary result; ornament aids in the expression of the whole and is consistent with it in general character and feeling. In short a certain spirit permeates the whole and this must be understood and felt before it can be properly imparted to new work. Obviously the most successful work in modern times is neither that which is most archæological on the one hand nor most free from suggestion of precedent on the other, but that to which the inherent character or spirit of past work has been imparted. And this, the highest level of achievement, is one in which the individuality of the artist most clearly reveals itself and in which that quality of fine architecture most distinctly comes into evidence, which we feel but cannot define,—the quality of distinctive individual character; the most admirable species of "Style"; infinitely to be preferred over pure historic style, however correctly this may be transposed from howsoever beautiful an original.

Methods of Construction, as the second of our limiting conditions, cannot be accorded the place they occupied as controlling factors in design when they comprised only the arch or the stone or wood lintel. The ancient necessity of using one or the other gave a simplicity and directness of force to the development of the several historic styles that is perhaps the reason of their inherent vigor and vitality. In our own time, when anything can be constructed of steel, however novel or difficult it may be, and when, as a rule, the great majority of buildings can be best built of forms which it seems most difficult to treat frankly and artistically, the temptation is great to treat structure and surface as independent of one another and as irreconcilable in their very nature. But this is not inherently true of any class of buildings and not true at all of some. We are in a transitional period and have only begun to grapple with the problem of how to treat the steel skeleton architecturally. Some progress has been made by the French, but this is in the use of the metal as both constructive and decorative material, so admirably managed in the Palais des Beaux Arts at the last Exposition. The problem of combining steel for construction and masonry for protection into a whole which shall give architectural recognition to both is as yet unsolved. But we of the new world are to do it.

Our next consideration, however, that of Materials, brings us face to face with conditions about which there is little of theory and much of plain duty. For here we may not take what we choose, but must choose the most suitable of that which is offered. This often seems unattractive or repellant, or at the best ill adapted to a proper color scheme or surface texture. But is this not often because local material will not so well adapt itself to a favored scheme of design? And is it not wise to consider this element with those of construction and plan as the factors which should dominate the manner or style of treatment? Surely no architecture has greater charm than that which seems indigenous, and of the very nature of its surroundings; a thing which could not have been produced elsewhere. This character is imparted most effectively by a judicious and tasteful use of native materials, whose color and texture as well as whose structural properties are carefully studied and intelligently employed.

Other considerations, such as unpromising peculiarities of site, and the restrictions of building laws and ordinances, make imperative demands upon the patience and judgment of the designer, but, from apparent obstacles may be turned to advantage under courageous attack. This is, of course, beside the question of accessories and surroundings from whose character and effect the building should never be separately considered.

This summary, while far from complete and greatly imperfect, yet presents some of the essentials of good architecture as it can and should be realized in our current practice. It is not doubted that difficulties beset the path of him who follows truth as the first principle of practice; who determines that his work shall be thoroughly and consistently designed in every respect. This path is not an easy one to travel but its pursuit means, to the individual architect, a growth of creative power and the maintenance of professional self respect, while to the profession it means whatever of progress may be made toward better quality of work, higher ethical standards and the elevating of the whole state of Architecture.

These are generalities, to be sure, and they glitter, be it frankly admitted, after the manner of their fascinating kind. One may reasonably protest that it is easy to theorize and to dream of a millenium but that we are confronted with stern and hostile realities; that one would willingly enough do better work if allowed the means with which to do it, but that clients are, as a rule, either unable to pay for what they want or are possessed of whims and prejudices equally fantastic and obstinate. There is no denying the force of this plea; these conditions are very real and very general and must be frankly faced.

Two remedies, however, present themselves with equal readiness, and both are based on education in its broadest sense. In the first place, to begin at home, we must train ourselves to absolute sincerity of attitude towards our work. There must be no mere striving for effect, no dragging in of artificial elements or suppression of those which have legitimate place. The nature of each problem must be carefully studied, its limitations recognized and its demands acknowleged. To reconcile these and work out the result in an architectural manner we must avail ourselves to the utmost degree of the means which lie at hand, and our materials must be studied with a view to their most effective use as regards construction, color, texture and possible ornament. The site and its environment must be accepted, not only as imposing difficulties upon the designer but as affording him a possible aid of the greatest value, if its own peculiar character be seized and echoed in his design. Other limitations, of whatever character, should be met and recognized in the general treatment of the problem. This does not imply a sacrifice of essentials, for if the artist be permitted, by his client, to make the best use of his materials the result may be entirely successful whatever the apparent paucity and barrenness of those materials. It may embody the best of qualities,—proportion and scale, excellence in mass and line, refinement and virility, appropriateness of ornament of whatever simplicity, and harmony of color. Above all, permeating the design, may be the evidence of good taste and the expression of individual character. Costliness is not essential to this result, but freedom is.

And at this point the education of the client is suggested. For our esteemed patron, as a rule, notwithstanding his virtues—perhaps indeed because of their very excess—is too little aware of our abilities and too prone to supplement them with his assistance, particularly in the field of Design. His control at certain stages of the work, and his cooperation at others, is indespensable, for he must pay for and use the building and his is the greatest loss if it prove a misfit. But if the structure be unsightly the loss is the architect's and once the practical requirements of the client are clearly understood and their attainment assured, the architect must be left free to grapple with the problem of design unhampered by the suggestions or mandates of the layman—that is, if the result is to be successful in the widest sense. Where a patron is a person of actual taste in these matters his cooperation with the artist is both a delight and an inspiration; but such a person instinctively recognizes the necessity of which I speak and prefers to leave the initiative with his architect.

The protest is entered against that spirit which so often shows itself in the attitude of clients who, while ready enough to entrust their architects with the difficulties of construction, are convinced that "all men are born free and equal" in matters of taste and that architects are engaged to carry out the pet fancies of the man who pays the fee.

The only effective means of changing this spirit lies in the power of the architect, both to do what is right and to persuade others that it is right. And this he cannot do if he be not himself convinced of the right. His convictions must be rooted in a sound training and the habit of study; must be nurtured by sincerity toward his art and be reinforced by a rational and open minded attitude toward its limitations. With these weapons some headway can be made against the worst case of obstinacy and domineering bad taste with which he is likely to deal and there are few laymen who will not feel and respect in an architect the force of deep and intelligent conviction, and who will not yield to it to a greater or less degree.

In this quality is found the most effective means of educating the client, and through him the public, and by this road lies the constant advancement of professional standards and the steady uplifting of architecture, whether it be as an art or a profession, or blending of both.

In this sense, then, is design an element of practice, that, broadly conceived, it underlies all that is of real and lasting excellence in the work of the architect.

THE IMPROVEMENT OF THE GROUNDS OF THE TORONTO INDUSTRIAL EXHIBITION.

When it was proposed last year to erect three new buildings on these grounds, one of them being of much greater area than any of those now in existence, it was felt by the members of the Toronto Chapter of the Ontario Association of Architects that the time was opportune for a re-arrangement and improvement of the avenues and grounds as far as circumstances permitted.

The development of a satisfactory scheme, and its adoption before the location and commencement of the new buildings, was considered to be a matter of paramount importance, as, one placed in a wrong position, changes or improvements would be permanently blocked or delayed for many years.

The Chapter spent many evenings in working out suggestions for these improvements, several members submitting sketches.

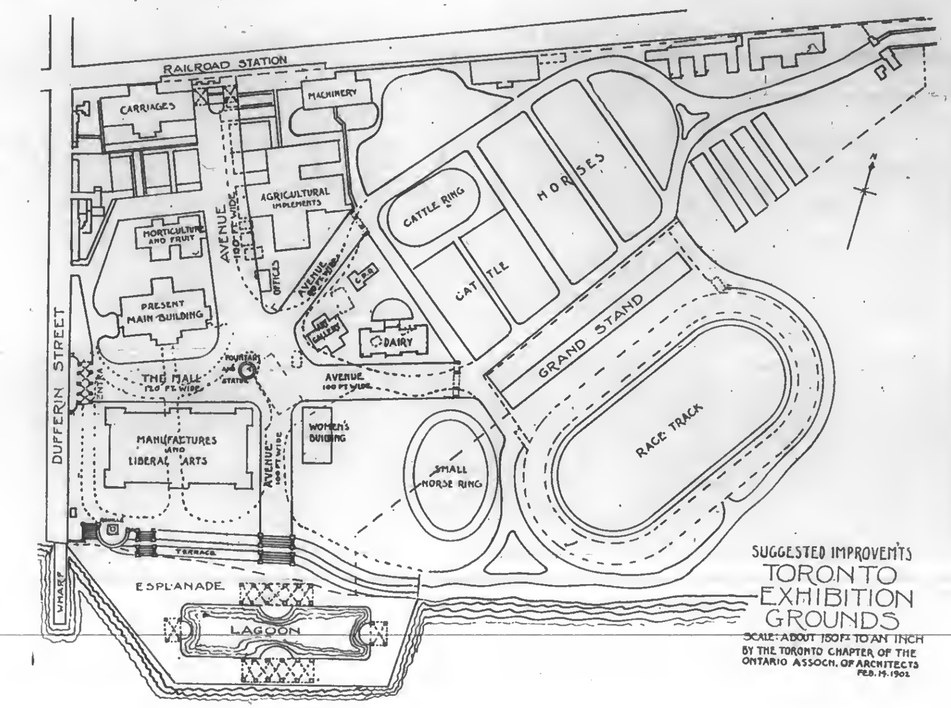
The good points of the various schemes were assimilated into the plan which was most favorably received, and although it was not felt that this plan was at all perfect, especially as the Chapter was in ignorance of some of the requirements, it was submitted to the Exhibition Board which passed it on to the Parks & Gardens Committee of the City Council.

instance as nearly as possible on the old walks and roads, which are indicated by dotted lines.

The making of the new avenues and the widening of the old may be spread over a series of years if necessary, and no large buildings, except those referred to, need be removed till they are worn out or obsolete.

The scheme, in brief, is as follows:—

The main avenue or mall 120 ft. wide to be located south of the present main building with appropriate entrance gateways on Dufferin street. The mall to open into a circle 300 ft. in diameter from which will branch avenues leading north, south and east 100 ft. wide, and north-east 80 ft. in width. The triangle between these avenues would be occupied by the art Gallery and the Dairy Building, while the Manufacturers and Liberal Arts Building would be located on the south side of the extension of the mall leading to the grand stand, and just west of the small horse ring, and not immediately south of the present main building as shown in the cut. This will permit the main avenue running north and south to be extended in a direct line to the lake. All these avenues to have their axis radiating from the centre of the circle, which would be their focal point, after the manner of the avenues in Washington, which are admitted to be among the finest and best planned on this continent.



Since the revival, with the new year, of the project of erecting the new buildings, a committee of the Chapter, in consultation with members of the Exhibition Board and the Park Commissioner, have evolved a modification of the former plan, eliminating the impracticable features and providing satisfactory sites for the proposed new structures.

It is not claimed for this plan that it is a complete or entirely satisfactory solution of the problem, as such is practically impossible under existing conditions, but it is claimed that it will be an immense step in advance of the present lay out of the grounds, and some approach toward the type of grounds so well illustrated in the planning of the Pan American at Buffalo.

The commendable features of the grounds at Buffalo were the broad Plazas, direct Avenues, well defined axis, interesting focal points, and well placed buildings.

Our scheme embodies these features as far as circumstances will premit.

The new buildings can be located in the positions shown with but little change, this year, in the roadways or approaches, while only one large building, (the Annex, or Women's Building) and three or four unimportant buildings will require removal.

It will be observed that the new avenues are located in every instance as nearly as possible on the old walks and roads, which are indicated by dotted lines.

It will be observed that the plan illustrating the above article does not correspond with the text. The location of the Manufacturers and Liberal Arts Building was changed after the engraving was prepared, and too late to alter it, as a result of a conference between the Park Commissioners, the architects of the building and the members of the Toronto Chapter, at this week's lunch.

The vistas at the ends of the avenues could be closed by appropriate architectural features such as a tower, arcade or pergola, while the circle could be accentuated by a generously proportioned fountain, embellished with groups of sculpture.

As the work of development went on year by year an esplanade could be formed at the mere expense of cribbing, the filling being done by the street commissioners department.

In this esplanade a lagoon or lagoons could be formed with appropriate architectural features on the margins.

If possession of the garrison commons should be acquired, the esplanade could be extended a long distance eastward, making a magnificent foreground or front to the grounds.

The banks along the shore, which are now but a disgraceful dumping ground for rubbish, could be terraced, with suitable balustrading and steps, making an unsurpassed vantage point for viewing aquatic displays in the lagoons beneath, or the lake beyond.

These suggestions are confessedly somewhat crude, and require working up into a systematic and well thought-out scheme.

This being done it should be quite practicable to do something each year, however little, towards the final completion of the scheme. The vital point is to secure and adopt a well devised plan now and adhere to it till the work is finished, be it ten or twenty years hence.

EDMUND BURKE,
Chairman of Chapter.

The Safety of Theatres.

Adverting again to this subject, to which some attention was given in our February issue, the important suggestion was recently made by a Mr. Mulholland in a paper read before the Playgoers Club of London, that a portion of the roof over the stage should be of glass, the breaking of which in the event of fire would draw off the smoke and flames from the auditorium. The advantage of this method of construction was proved in connection with a fire in the Grand Theatre, Islington. One of the greatest dangers to which an audience is exposed when a fire occurs in a theatre is from suffocation by smoke, hence the value of the above suggestion.

An Out-of-Date Building By-law.

The City Engineer of Johannesburg, South Africa, recently made request of the City Engineer of Toronto for copies of regulations governing the use of iron and steel in building construction. The City Engineer of Toronto in his reply was compelled to make the humiliating confession that the Toronto Building By-law makes no reference to or provision for this form of construction. It might with equal truth have been stated that the by-law is in a hundred other particulars twenty years behind the times, and that the only effort to bring it up-to-date was made, not by the City Council, but by an outside body, the Ontario Association of Architects, the result of whose labors in the form of a draft by-law submitted to the Council, was pigeonholed some eight or ten years ago, and has never been heard of since.

Shingling Brick and Stone Walls.

The walls of some new houses now under construction in Toronto will be covered with wood shingles down to the level of the first floor. The shingles are nailed to strips of wood inserted for the purpose in the joints of the brickwork. The architect has two purposes in view in using this method of construction—first by means of horizontal lines to reduce the apparent height of the buildings and secondly to secure warmth and dryness. As regards the first of these, he is of opinion that a fault in the design of most of our residential buildings is their too great height, largely due to the free use of vertical lines. The use of shingles on brick and stone walls as a means of protection from wind and rain, has long been common in some of the country districts of the province of Quebec, as well as throughout the provinces of New Brunswick and Nova Scotia. In Quebec the north and east sides only of dwellings are frequently protected in this manner. In some cases outside stone walls are plastered with cement without the use of furring, the cement being put on with a trowel.

Women Practising Architecture

The first paper ever presented by a woman before a society of British architects was read by Miss Ethel M. Charles at a recent meeting of the Architectural Association in London. The paper was entitled "A Plea for Women Practising Architecture." The author has taken the student's course and passed the examinations of the Royal Institute of British Architects. She cleverly marshalled arguments in support of her contention that women possess equally with men the essential qualifications necessary to success in the practice of architecture. She instanced the fact that women are employed in the heavy work of chain-making and in the harvest fields as a proof of their ability to withstand physical strain. While not admitting their inability to climb ladders, she suggested as a means of overcoming the possible objection to them being seen climbing ladders, that women architects should, like Christopher Wren, be hoisted up in a basket. The achievements of women in the universities even in such subjects as mathematics and logic, were cited as evidence of their mental ability to deal with matters of a scientific and practical nature. On the artistic side it was claimed that their natural qualifications are superior to those of men. It was contended that a practical training in the workshop has ceased to be a necessary part of the training of an architect, intellectual activity rather than manual skill being the sine qua non of success. The lack of creative power in women was admitted, but the increasing self-reliance of the sex gave foundation for the hope that this power, long dormant, might be roused into activity. In the discussion which followed the reading of the paper, most of the speakers doubted the ability of women to successfully perform all the duties of an architect, especially to deal with contractors. At the same time there was manifested a disposition to give them the opportunity to try. The adaptability of women for office work, for the planning of domestic buildings and for work of a decorative character was fully recognized.

The Beautifying of Cities.

THE movement for the beautifying of cities is rapidly extending. It is gratifying to note the remarks of Mr. A. E. Ames, President of the Toronto Board of Trade, on the necessity of a definite plan for the improvement of Toronto. Mr. Ames suggests the expenditure of a reasonable sum by the City Council to secure the services of a competent person to prepare a comprehensive plan for the beautifying of the city, this to be followed by the procuring of legislation authorising the appointment of a commission to adminster funds for carrying out the plan adopted. Mr. Ames is quite right in his opinion that such a plan would secure better results than the present method of sectional improvement. The Ontario Association of Architects has been asked to support a movement to have plans prepared by an expert for the beautifying of Toronto Island. A great improvement has been effected on the Island in recent years by the efforts of the City Commissioner and Park Commissioner, but these improvements would be greatly enhanced by the preparation of a definite and comprehensive scheme to the completion of which all future efforts should tend. Every scheme for the beautifying of cities should include the architecture of at least the principal thoroughfares, and especially buildings of a public character. An important step in this direction has just been taken in New York by the introduction of a bill, drafted by the New York Chapter of the American Institute of Architects, in the New York Legislature, providing that the Mayor of New York shall, before the 1st of June next, select from a list of 100 names, presented by the Fine Arts Federation, 50 architects who shall be declared to be "eligible architects for municipal work" and who shall carry out all architectural work undertaken by the city in the future. Provision is made for increasing the list to 100 names, after which vacancies will be filled only as they occur. The selection of architects for this list is not restricted to members of the profession resident in New York, but may include architects of standing in any part of the country.

Toronto Building By-law.

In June of last year some amendents were made to the Toronto Building Bylaws. The following section numbered 13a. was added to By-Law No. 2468 :

13a. As soon as all buildings in process of construction are up one storey high, and joists on, the said joists shall be covered or floored temporarily, or otherwise with inch boards, as each storey is built ; in cases where joists are over sixteen inches up to four feet centres, one and a half inch plank shall be used ; and where joists or beams are over four feet up to six feet centres, then two inch plank shall be used, or else two one-inch boards laid one on top of the other. In case of steel structures where the girders are twelve feet centres, two-inch plank shall be used with sufficient support in the centre."

The City Commissioner has recently notified the city contractors that compliance with this section of the By-Laws will be enforced, and that those who fail to comply with the provision will be summoned to the Courts. It will be noticed that the By-Law does not stipulate by whom the temporary floors are to be constructed. By request of the Builders' Exchange, the Toronto Chapter of the Ontario Association of Architects have appointed a committee to discuss with the builders in what way compliance with the By-Law should be made. It is clear that a temporary floor must be provided by someone. The question is whether the carpenter or bricklayer will put down the floor. The absence of a definite understanding on this point would, the builders claim, result in each of these contractors feeling under obligation to furnish the floor and charge the cost in his tender. The suggestion has been made that architects should in every case specify double floors. This is said to be the practice in the United States. We imagine, however, that architects would hesitate to saddle their clients with this extra expense, which, in the case of large buildings, would amount to a large item. Judging by the record of accidents in recent years, this amendment to the By-Laws does not seem to be necessary, and the results in the direction of increased safety to workmen are not likely to be commensurate with the trouble and expense involved. At the urgent request of the Trades and Labor Council, a city scaffold inspector was recently appointed, and it may be that this and other amendments are necessary to provide this official with employment. The amendment in question serves to illustrate the unwisdom of fragmentary changes of this character in the By-Laws. What is required is a careful revision of the regulations as a whole.

PRINCIPLE AND METHOD.

The paper on the Field of Decorative Art, printed on another page, and the discussion which followed the paper, suggest a great want in the literature of architecture. Book upon book has been written upon the historical development of architecture, but always regarding it as a historical document. The sequence of styles is perfectly established, but to whom is it of real use except to historians ! Architects value books on the subject chiefly for their illustrations, and use them, not for the purpose with which the book was written, but to help themselves in some way to design modern work. In other words every man, unconsciously or half unconsciously, makes for himself, according to his light, rules founded upon the principles of beauty, that is to say the causes of attractiveness, in the buildings he is studying, in order that he may bring into being, not the same design, which he knows to be impossible (if he is experienced), but the same attractiveness, and for the same reason, in his own work. It is needless to say how slow this process is and how ineffectual in many cases, where nevertheless the beauty of the building studied obtains full appreciation. A mind capable of conception is very often not strong in analysis. It wastes time and energy in feeling its way to the results. What is necessary to enable it to work rapidly and surely is a framework of principles and method supplied from without. This is the real use of the architecture of the past to the architects of the present—as architects; to supply models from which the causes of beauty may be deduced. It is only upon some such scientific basis of design that it is possible to invent with ease. No man can mass design by accident, and it is in massing that design really consists. As all design consists in this, all ages supply matter for its illustration. Yet how little has been said about it. We learn in works on architecture that the Greek pediment was low in pitch, that the Romans pitched their pediments higher and the Gothic designer's gable was highest of all ; but no lesson in design is drawn from this. We learn in every case merely what the designers of a period did ; and, so far as construction in design is conveyed at all, we are taught only how to carry out historical unity in design. Experience teaches that there is more in preserving historical unity than the mere avoidance of offence to the eye of the educated. We avoid also offence to the educated eye. A mixture of different historical characteristics is fatal to the harmony of design. Knowing this, but not knowing clearly what is essential and what is not, the wise man goes by his book ; and as he becomes skilled in the styles, comes, as all men do, to enjoy his skill, and love correctness for its own sake. That is to say from hatred of solecism he commits a wholesale solecism every time he builds.

This is not much to show for a faithful study of architecture. There must be more to be got out of it than that, the lesson of the history of architecture should be, not what the past designed, but how it was designed. The beauty of every great example has a reason. To return to the three classes of gables—there is reason, as shown by John Beverley Robinson, for the varying pitch. The Greek front, solid widely spread, is suitably finished with a low pitched gable, while the Roman, more slender and vertical, naturally cocks it up and the Gothic more again. This is the kind of truth we should learn from the history of architecture. To know how to be Greek or how to be Roman or Mediaeval is merely to put one's self in fetters. To know why all three were good is to give one's self the freedom of design in any age—even in our own.

Mr. H. G. Wells, who is so fond of carrying his scientific observations into the future, has, in his new book of "anticipations" about the state of the world in the year 2,000, some speculations about the conditions of building. He is of course heartlessly scientific and says, (I quote at second hand) that he expects the engineers of the future to be the great men of their time, but the architects to be opposed to progress, because they are "too highly cultured and not sufficiently educated." By "cultured" he evidently means trained in precedent, and by "educated" trained in science. Making allowances for his scientific point of view, and the probability that his idea of an architect's education is limited to a study of the properties of iron and concrete and sewage, the accusation, whether it is likely to be justified, or not, gives a judicious pointer as to the need of more scientific education for architects in the future ; an education which shall be scientific in all directions ; in design as well as in construction. The constructor has become inventive ; the designer must become inventive too. I am well aware of the horror of lean iron forms, and of the necessity of forming new ideas of beauty, that the idea of architectural invention brings before a well regulated mind. But surely to study the principles of design is the very way to prevent the realization of this horror. There cannot be more than one set of principles of beauty in this world, even if it is possible to conceive of there being another set in any other world. It looks therefore as if to take Mr. Well's advice and devote ourselves more to "education" and less to "culture" is the surest road to making beauty keep company with the necessity that is coming to us of keeping design abreast with construction in our own times.

But a new departure in design is not what this article is about. It is clear that principle and method are the only road to such a departure when it becomes necessary. Culture, in Mr. Wells sense, has already met a Waterloo in the tall buildings of New York. In their case, it is not until the dusk comes on, to obliterate

their architectural treatment, that a consciousness of their greatness is not obscured by a perception of their littleness. It must be possible to make more of such opportunities than that, and it is clear from the failure of the early efforts in this kind of building that Vitruvius is out of it this time. A study of the principles of design is particularly necessary for these problems which therefore bear essentially upon the argument; but the purpose of this article is to advocate the acquisition of familiarity with principles and facility in method for the purposes of ordinary design. All design requires it, the simple as well as the stylish; and the most affectionate adaptation of old work would be better done if the principles at the bottom of the original were open to the eye as well as the result.

Where then are these principles to be found that we may acquire them? That unfortunately is the difficulty in this matter. That is the want spoken of above, in the literature of architecture. They exist, there is enough evidence to show that. And the definition of many of them exists too, scattered here and there through the works of writers on art. Every architect has found out some for himself, and if he turns his attention particularly in that direction, will find out more. Gwilt enters into the elusive question of proportion. So does Viollet le Duc in his Lectures on Architecture. One can hardly come out of a study of these investigations without some serviceable addition to method in setting up a design. There are suggestions for practice to be gleaned from H. Heathcote Statham's Architecture for General Readers. But the most enlightening and serviceable attempt is that of John Beverley Robinson in his Principles of Architectural Composition; which he describes in his subtitle as "An attempt to order and phrase ideas which have hitherto been only felt by the instinctive taste of designers." With these books at hand. and particularly the last, we have not such a bad showing for our purpose after all. The books are all in the library of the Ontario Association of Architects.

The papers read before the Royal Institute of British Architects are very often concerned with principle and method, and a useful collection might be made from them of the opinions of practising architects upon these points. It would be even more useful if our own architectural associations devoted themselves to putting together their ideas in the form of papers upon this subject. An original paper of any kind blesses him that gives as well as him that takes. To set in order what he knows, or to classify and arrange what he can glean from books, or even to boil down John Beverley Robinson for his own personal use, is an exercise which would well repay the time expended upon it by an architect, and would be a useful contribution to the proceedings of his association.

No doubt something to this purpose can be gathered from Ruskin's architectural works; but, as the investigations of the Stones of Venice are directed towards the evidence of character in architecture as found in the detail, his principles are concerned more with conception and character in architecture and beauty in detail than with the composition of masses. In Ruskin's Elements of Drawing, the composition of landscape is considered and these rules are of course of general application—for any one who is capable of applying them.

It is this capability which we may expect to be the fruit of studying the principles of beauty in architectural composition and practising methods for their scientific application in design. The adoption of John Beverley Robinson's rules in something of the rule of of thumb manner will keep a man from being a fumbler; but, to be at home with the principles of beauty, and to have an instinct for method so as to compose with ease, one must look for these principles in all kinds of composition and study every method that holds out the hope of putting them together with some approach to geometrical certainty.

W. A. Langton.

BRITISH, CANADIAN AND UNITED STATES ARCHITECTURE.

An English architect who visited Toronto recently expressed appreciation of the merits of much of the domestic work under construction and recently completed in that city. In view of the proximity of Toronto to the United States, he was surprised to find the modern architecture based so largely on English instead of American lines. Even American architects, he thinks, are following, to some extent, British precedent, especially with regard to planning. In buildings of a public character, however, Americans are largely influenced by the traditions of the Beaux Arts School at Paris. They have sufficient invertiveness, however, to impart originality to the style, and to adapt it to the requirements of this Continent. In buildings of this class the English architect, as a rule, is less successful. This is believed to be due to the limited size of the sites and buildings with which he has principally to deal. Not only are the sites in most instances very limited in area, but very irregular, so that it is not possible to give to the buildings the bold treatment which is so characteristic of large buildings in the United States built on rectangular sites. Even the Germans, who have little to say in praise of English architectural design admit the skill displayed by English architects in planning. This skill is largely the result of the necessity of adapting buildings to irregular sites, while the regularity of the sites of the majority of large buildings in American cities renders planning of such structures comparatively easy. Another hindrance to broadness of effect in English street architecture is the fact that nearly all the land is leasehold. Leases belonging even to the same estate, expire at different periods, thus preventing the carrying out of any general scheme of improvement of the street frontage. Such improvements as may be made are usually arranged for when the lease of the land on which the building stands runs out. The improvement thus relates only to the individual building and uniformity of design and effect is not obtainable.

Mr. J. Wilson Gray, architect, has removed his offices from the 3rd to the 6th floor of the Confederation Life Building, Toronto.

Messrs. Burke & Horwood, architects, suffered heavy loss in books, drawings, etc., by the fire which partially destroyed the Union Loan Building, Toronto, on the morning of the 3rd. inst. Fortunately their drawings of current work had been placed in the vault, and thus escaped injury. Messrs. Burke & Horwood have temporarily removed their offices to No. 15 Toronto street. The Toronto Chapter of Architects, of which Mr. Burke is chairman, passed a resolution expressing the sympathy of that body with Messrs. Burke & Horwood in their misfortune.

INTERCOMMUNICATION.

[Communications sent to this department must be addres ed to the editor with the name and address of the sender-atta hed not necessarily for pub ication. The editor does not hold himself responsible for the expressions or opinions of corre pondents, but will, nevertheless, endeavor to secure c rrect replies to queries sent in. We do not guarantee answers to all queries, neither do we undertake to answer questions to issue following their appearance.]

From "Builder":—What is the rule for finding the length of braces between two posts when they incline one foot in six feet rise?

Ans.—Suppose the illustration, Flg. 1, represents a frame, the posts of which incline one foot in six feet

Fig. 1.—Getting Length of Braces.

rise. Let the distance B B represent a distance of seven feet. The braces are run at an angle of 45°. The posts inclining one foot in six leaves the distance at A A six feet. The length then may easily be found by using the steel-square which will also give the bevels of the joints. In this case the actual length of brace from point to heel is 8 ft 5 3-16 inches. The square may be applied 6 times, using 12" mark on the blade and 12½ inches on the tongue—then lay out, the same as laying out rafters.

From "A Village Contractor":—Will you please inform me of the method generally adopted for measuring masonry, both before and after being built?

Ans.—Stone masonry is measured by two systems, and they are again subject to local usage. These systems are called quarryman's and mason's measurements. By quarryman's measurements the actual contents are measured—that is, all openings are taken out and all corners are measured single. By mason's measurements corners and piers are doubled, and no allowance made for openings less than 3x5 feet, and only holf the amount of openings larger than 2x5 feet. Range work and cutwork are measured superficially, and in addition to wall measurement. Rough stone walls are measured by the cord of 100 feet in the wall, or 128 feet loose on the ground, and all openings less than 3x3 feet are counted solid, and half of openings above that size are counted as solid walls, to which must be added 18 inches running measure for each jamb built. Arches are counted solid from their spring. Corners of buildings are counted twice. Pillars less than three feet are counted on three sides as lineal, multiplied by fourth side and depth. It is customary to measure all foundations and dimension stone by the cubic foot, water tables, base courses and similar work by lineal feet. All sills, lintels, and ashler work by superficial feet, and no wall less than 18 inches thick. To lay a cord of stone of 128 feet loose will require three bushels of lime and a cubic yard (27 cubic feet) of sand, and when laid in wall the whole will measure 100 cubic feet, or one mason's cord.

Brickwork is generally measured by the 1,000 bricks laid in the wall. In consequence of the variation of size of bricks, no exact rule that will apply to all localities can be laid down. The following, however, is a fair average for Canada or Ontario at least, and is adopted generally by the Ontario Association of Architects:

For a	4¼	inch or veneered wall,		6½	inches
"	9	"	wall	13	"
"	14	"	"	20	"
"	18	"	"	26	"
"	22	"	"	32½	"
"	27	"	"	40	"

This rule may vary from one-half to one brick for each superficial foot in a wall, according to size of bricks, but not any more. If the bricks are large, the number per foot of wall may be one brick less than given in rule; if smaller, the number per foot may be increased by one foot or less. This rule is based on a standard size of 8¾ x 4¼ x 2⅛ inches. Corners are not measured twice as in stone-work. Openings over 2 feet square are deducted. Arches are counted from the spring. Fancy work counted 172 bricks for one. Pillars are measured on their face only.

A cubic yard of mortar requires one cubic yard of sand and nine bushels of lime, and will just fill thirty hods. One thousand new bricks closely stacked will require 56 cubic feet of space. One thousand old bricks cleaned and loosely packed occupy about 72 cubic feet. Five courses of bricks laid in a wall should make one foot in height of wall or chimney. Six bricks in a course will make a flue 4x12 inches, and eight bricks in a course will make a flue 8 inches wide and 16 inches long. Bricklayers generally contract for laying bricks by the 1000 in the wall, and the prices vary according to cost of materials and price of labor.

From "A Mechanic":—Will you please explain how the different "cuts" for mitres, octagons and hexagons, are obtained by the use of the steel square?

Ans.—Note the diagram, Fig. 2. Here we show a quarter of a circle x A C, along the horizontal line A B,

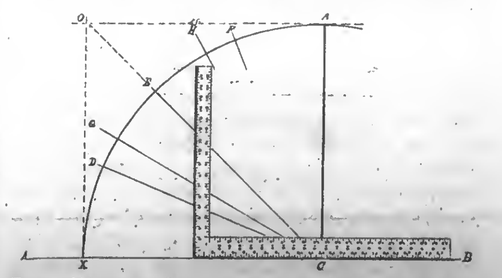

Fig 2.—Method of Obtaining Cuts for Mitres, for Square, Octagon and Hexagon, by Aid of the Steel Square.

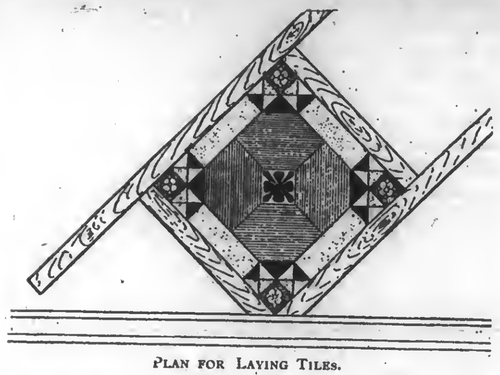
the square is laid with 12" on the blade at the centre C, from which the quadrant was struck. If we divide this quadrant into halves we get the point E, and a line drawn from 12" on the blade of the square and through the point E, we cut the tongue of the square at 12" and through to O, and the line thus drawn makes an angle of 450, a true mitre. If we divide the quadrant between E and X, and then draw a line from C, a 12" on the blade

of square, cutting the dividing point D, we get the octagon cut which is the line C D. Again, if we divide the space between E and X into three equal parts, making G C one of these parts, and draw a line from C to G cutting the tongue of the square at 7″, we get a cut that will give us a mitre for a hexagon, therefore, we see from this, that if we set a steel square on any straight edge or straight line, with 12″ and 12″ on blade and tongue on the line or edge, we get a true mitre by marking along the edge of the blade ; for an octagon mitre, we set the blade on the line at 12″, and the tongue at 5″ and

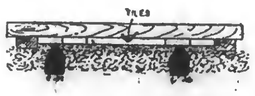


PLAN FOR LAYING TILES.

we get the angle on the line of blade—nearly—and for a hexagon cut, we place the blade at 12″ on the line, and the tongue at 7″, and the line of the blade gives the angle of cut—nearly. The actual figure for octagon is 4 31/32 but 5″ is close enough, and for a hexagon cut, the exact figures are 12″ and 6 15/16, but 12″ and 7″ is as near as most workmen will require, unless the cut is a very long one.

From "A Subscriber":—I have a "tile-floor" to lay in a store, and, having had no experience in this kind of work, would like a few "pointers" as to how the work should be done?

ANS.—In the first place, if the tiles are to be laid on wooden joists, the joists must be deep, say 2″ x 12″ or 3″ x 10″. The tops of the joists must be bevelled off to the centre, making the top like an inverted Λ, and the spaces between the joists must be boarded down about



SECTION FOR TILE-LAYING.

five inches from the top edge of the joists. On the top of the boarding must be laid concrete to the level of the joists and the whole smoothed off, and while damp a proper layer of Portland cement, not less than an eighth of an inch thick must be floated on the concrete, and on this the tiles must be laid even and level. The tiles must be well soaked in clean water before being laid on the cement. In laying tiles, always begin work in the centre of the room, and work all round until the work is completed. It is best to set straight-edges, level and out of wind with each other, then set all tiles level and true with thin gauges as shown in the illustrations. This will insure a neat and level job of work.

TESTS OF DOUGLAS FIR.

Builders are familiar with the fact that Douglas fir is among the strongest woods in the world, but figures such as have been prepared for the British Columbia Mills, Timber & Trading Co., of Vancouver, are of especial value to those interested in the subject. This company sent five fir logs to the testing and experimental works of David Kirkaldy & Son, of London, England, to be subjected to the severest bending and thrusting tests, and full data to be returned. The results show in detail that fir is in every respect satisfactory to those who have always insisted that it was one of the best varieties of wood.

The specimens give the bending test 12x15 and 16 inches in dimensions, cut to a length of 13½ feet, with a distance of 12 feet between the supports and the load applied at the center. The mean total stress in pounds and deflection in inches are shown in the following table :

Weight.	Deflection.	Weight.	Deflection.	Weight	Deflection
10,000	.027	34,000	.365	58,000	.663
14,000	.119	38,000	.414	62,000	.726
18,000	.170	42,000	.461	66,000	.804
22,000	.219	46,000	.511	70,000	.911
26,000	.269	50,000	.561	74,000	1.070
30,000	.317	54,000	.613	*78,000	1.203

*Only three pieces were given this strain.

The ultimate weight borne by the pieces was 78,714 pounds, or 35.1 tons, which was equivalent upon the beam of 93,162 pounds, or 41.6 tons. The timbers were bent to a deflection of five inches and removed.

Those tested to ascertain the resistance to depression were 12x12 and 100 inches long, with the ends faced true in a lathe. The total stress in pounds and depression in inches were as follows :

Weight.	Depression.	Weight	Depression.	Weight	Depression
40,000	.027	220,000	.114	400,000	.195
60,000	.038	240,000	.122	420,000	.205
80,000	.048	260,000	.130	440,000	.214
100,000	.059	280,000	.139	460,000	.225
120,000	.069	300,000	.149	480,000	.243
140,000	.078	320,000	.157	*500,000	.238
160,000	.088	340,000	.165	*520,000	.253
180,000	.097	360,000	.175	**540,000	.250
200,000	.106	380,000	.184	**560,000	.267

*Only three pieces subjected to this strain. **Only two pieces subjected to this strain.

The average ultimate strain of the five pieces before they were crushed was 531,656 pounds, or 3,680 pounds to the square inch, although two of the pieces withstood a stress of more than 4,000 pounds to the square inch.

CURIOUS CEILINGS.

A Russian nobleman has hit upon a curious method of ceiling decoration. Every ceiling in his mansion contains a fresco dealing with an episode in the career of his ancestors and the whole forms what is perhaps a unique example of inner roof ornamentation. Nearly 500,000 roubles has been expended upon this extraordinary work, a sum equal to approximately £71,500. Less extravagant, but undoubtedly quite as curious, is the ceiling decoration of a certain London house-holder, who has covered the surface in question with cancelled cheques returned to him through his bank. At first glimpse the real nature of this quaint embellishment is not apparent to the spectator, but the effect of same is said to be positively charming.

Chromes should not be mixed with ultramarine, which contains sulphur, as they would eventually turn brown, forming black sulphide of lead.

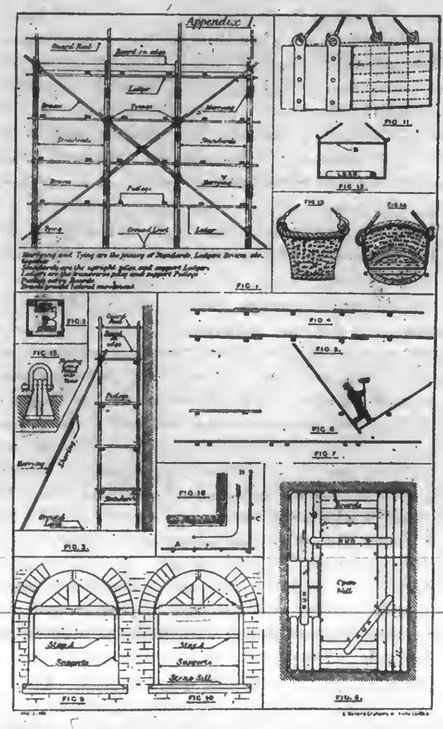
ACCIDENTS ON BUILDINGS.

The subjoined memorandum on the causes of common accidents that occur on buildings in course of construction or repair, and hints for their prevention, has been issued from the British Home Office. The modifications introduced have been made upon the suggestions of leading experts who have been consulted :—

In the following memorandum, reprinted from the Builders' Reporter and Engineering Times, an attempt is made to explain and illustrate those accidents, the causes of which may be considered controllable by the builders and workmen.

The dangerous conditions in building operations may be divided into two classes—(a) those arising from imperfect scaffolding, and (b) those arising from the lifting and carrying of material.

SCAFFOLDING--1. The two principal methods are known



respectively as the north and south country systems. The northern, as the names indicates, is principally used in Scotland and the north of England, although of late years it has also found favor in the south; the other method (see fig. 1) is essentially the south country system.

2. The first method is invariably used in conjunction with power, generally a steam crane. When one crane only is necessary it is fixed upon a triangular platform built upon three legs, one at each angle, and is raised to such a height as to be well over the building to be erected. The crane stands over the principal or king leg. Owing to the guys it cannot make a complete revolution; if power is required that can be utilised on all parts of the building, the erection has a square platform with a leg at each angle ; two cranes are then fixed, being placed diametrically opposite to each other.

3. The three or four legs, as the case may be, are of framed timber, bolted, and are weighted to the ground by masses of brickwork. The whole is so well built that accidents occurring through faults of construction are extremely rare.

4. The greatest dangers arise when the crane is imperfectly fixed, and when the weight of the crane engine and load is too much for the king leg on which it rests, and when the legs are not sufficiently far from the king.

5. With regard to the first point, the guys of the crane should always be carried to the centre of the secondary legs and chained down to the masses of brickwork which weight these legs at their feet. This chain requires frequent examination, especially when a heavy load is being raised, as, owing to the vibration of the scaffold, it becomes loose, and if not tightened the crane would lose its rigidity and accidents would be likely to occur.

6. In the second case, where the weight is great, the king leg should have an additional centre upright running from top to bottom. (See fig. 2, which is a plan of a king leg.)

7. The second form of scaffolding presents many points of interest. In order to render this report more intelligible, notes are given on the sketch (fig. 1) which explain the technical terms used. There are two varieties, again, of this form of scaffold, and their use depends upon the material of which the building is being constructed, viz., either of brick or stone.

8. Where bricks are in use one row of standards and ledgers only are necessary, the putlogs resting outwardly on the ledgers and inwardly on the wall (where header bricks have been left out for their reception.)

9. On stone buildings, and more especially when ashlar fronted and where an opening in the wall would leave a permanent disfigurement, a double set of standards, &c., are necessary to carry the putlogs. (See fig. 3, which is a section of what is known as a mason's scaffold.)

10. A few points with regard to these erections.

11. The different marryings, tyings, &c., should be carefully watched, as scaffolds have been known to come down owing to the cords slipping. This happens more especially when the cords have been used damp, the influence of a hot sun causing them to relax considerably. Wedge driving between cords and posts is the usual method of tightening.

12. The boards on which the men work should be carefully kept in position. Fig 4 shows the usual position of the boards. Carelessness may and does result in these losing their place, and if by so doing they take the position shown on fig. 5, what is known as a trap is formed. Fig. 6 illustrates the working of a trap. It will be noticed that when on the boards it is not easy to tell where the putlogs are. This creates to a great extent the danger. A certain preventative would be for the putlogs to be used in pairs, the boards then instead of overlapping could be placed end to end (see fig. 7); in overlapping boards get out of place, and a second man or two may catch his toe against the end raised.

13. Two of the commonest forms of accidents occur on these scaffolds, the falling of the workmen, and the dropping of the material from the upper floors of the erection. On the outside of the scaffold, also at the

ends, a guard rail should be lashed to the standards about 3 feet 6 inches above the scaffold boards. This would obviate the first danger. With regard to the second the danger from falling material is much to be deplored, as though it can occur in many ways, it is, as a rule, the result of great carelessness. A board on edge running along the outside of the scaffold, but within the uprights and nailed to them, and again at the ends, would, to a great extent, prevent this class of accidents. Unfortunately this board cannot be fixed on the inward side of the scaffold, as it would interfere with the free use of the workmen's tools. Figs. 1 and 3 show the guard rail and board on edge.

14. A mason's scaffold should be supported in such a manner that no opportunity could occur for it to fall away from the building. Fig. 3 shows the shoring, which is the usual method of preventing this where room permits; but this cannot be applied in a street, and in that case the scaffold should be tied to the inside of the buildings by poles through the openings.

15. There are other conditions of risk involved in insufficient width of runs, and in the use of centreing improperly supported. A run is commonly seen only one board wide (9 inches). It is needless to say that this width is dangerous; 18 inches is the least that should be allowed. A run for continued use would be better made of two 3-inch by 11-inch planks if two planks are used. A slip of wood can be nailed across the undersides to keep them together. Fig. 8 is a plan of a working platform surrounding a courtyard or well, and gives three examples of runs which are commonly used, but which are not satisfactory.

16. Improperly supported centreing is seen only in cheap work. Figs. 9 and 10 give an example of what is meant. It will be noticed that the supports to the centreing of fig. 9 are kept in their position entirely by the lateral pressure exerted by the stay A. It follows that if this pressure is eased sufficiently, say by shrinkage, it is more than probable that the centreing and a large portion of the unfinished arch would fall. Fig. 10 shows the centreing properly supported. All supports to centering should rise from a solid foundation.

16A. Painters' boats occasionally fall owing to the use of defective cordage and supports. Care is the only remedy that can be suggested.

16B. Gantries, especially those erected over the public way, having to carry great weights, should be effectively strutted and braced, and timber of sufficient strength used.

THE LIFTING AND CARRYING OF MATERIAL.—17. Very little danger arises during the lifting and carrying of material so far as the power in use is concerned. The accidents generally occur owing to the defective manner by which the material is secured to the crane, pulley wheels or whatever the arrangement for lifting may be.

IRONWORK.—18. Ironwork is principally used in the forms of girders or columns. They are sometimes slung by a chain around the middle and as evenly balanced as may be. There is considerable danger of this chain slipping, however well balanced (more especially if the load when swinging is tilted, say by receiving a jar through touching some part of the erection) and thus allowing the material to fall. To prevent this a second chain may be run from each end of the column or girder to a point some distance up the supporting chain, but the best remedy is a "softener," i.e. an old bag or sack put round the ironwork first, and the chain turned twice around it over the "softener" and knocked as close as possible, then no slipping will take place.

The same applies to timber.

TIMBER.—19. Timber in lengths can be carried in the same manner as the iron girders, but owing to the greater friction set up between wood and iron it is not so likely to slip as the former. The same precautions however, are necessary.

BRICKS, SLATES, ETC.—20. Bricks, slates, &c., in large quantities are slung in crates, in smaller quantities in baskets, and in small work are carried in hods by laborers.

21. The crates (fig. 11) will carry as many as 350 bricks. It will be noticed that they are not fitted with sides. This is to facilitate loading. The chief danger arises from their use when they are improperly packed. When suspended the pull on the handles causes the ends to take an inward slope. If the crate is tightly packed this pull creates a pressure on the material, and tends to keep it in position, but if loosely packed the absence of sides would be a source of danger, as the material could easily fall out.

22. If a similar crate was used to carry a roll of lead, it would be necessary to place a stay, (B, fig. 12) across the top to counteract and relieve the strain at the bottom.

23. When baskets are used the danger lies in the handles. If they are hooked to chains, which is the usual method (Fig. 13), the weight may and does cause them to give way. One remedy is for the chain or rope to be carried around the basket, as shown in Fig. 14. The pieces of wood marked R, if fixed as shown, would give the basket a level bottom, and would also tend to prevent the rope slipping. A better course would be so to construct the basket that the material of which the handles are made should be carried down the sides and along the bottom of the baskets and well secured thereto. In any case care should be taken to see that the baskets are strong enough in the first instance, kept in proper repair and not overloaded, and that spring hooks be used on the slings.

STONE.—24. There are several methods of lifting stone. It can be lifted in the same manner as ironwork, or may be suspended by means of a "lewis," or again by means of nippers.

25. The first method is perhaps the safest, but is generally used for undressed work only, as the chain is apt to break up any finished edges, etc.

26. The second method—by a lewis. A hole is cut into the stone wider at the bottom than at the top, three pieces of iron, as shown on fig. 15, are fitted into it, the outside or splayed pieces first, and the rectangular centre piece last. A bolt running through the top of each fixes its position, and at the same time secures a ring into which the hook, by which it is to be lifted, is placed. This arrangement will lift a very great weight, They are made in all sizes to suit; the softer the stone the deeper they ought to be in proportion to the weight. The risk of its giving way if the stone is not free from vents, or when the lewis does not fit the hole, or again, if the weight is not evenly distributed, is considerable. Its use with perfect safety can only be left to the judgment of the mason.

27. The nippers clutch the stone on the outside. Danger may arise if the small holes picked out to receive the nippers are so near the top edges of the stone that the points drag out; or again, the centre of gravity may be above the points causing the stone to turn over and fall.

28. It is, of course, assumed that the plant in use has been, both in point of quantity and quality (and the first is of equal importance with the second), fully sufficient. It is regrettable that often in actual practice this has been fuund not to be so. Inferior tackle has been and is responsible for many accidents. Many lives, again, could have been saved if a little forethought had been used, and compliance made with those unwritten rules by which workmen should be guided. Fig. 16 will give a clear illustration of what is meant. A labourer in building a scaffold required a ledger at point A. He fetched it from point B. He carried it upon his right shoulder, and in turning the corner in the direction of the arrow the end of the pole struck against standard C. The recoil immediately knocked him off the scaffold. If the pole had been on his left shoulder the blow would have fallen harmlessly, and his life would not have been lost.

The following suggestions, if carried out, would tend materially to reduce the number of accidents occurring on buildings in course of construction or repair:—

(1) All working platforms above the height of 10 feet taken from the adjacent ground level should, before employment takes place thereon, be provided throughout their entire length on the outside and at the ends—

(a) With a guard rail fixed at a height of 3 feet 6 inches above the scaffold boards. Openings may be left for workmen to land from the ladders and for the landing of material.

(b) With boards fixed so that their bottom edges are resting on or abutting to the scaffold boards. The boards so fixed should rise above the working platform not less than 7 inches. Openings may be left for the landing of the workmen from the ladders.

(3) All "runs" or similar means of communication between different portions of a scaffold or building should be not less than 18 inches wide. If composed of two or more boards they should be fastened together in such a manner as to prevent unequal sagging.

(4) Scaffold boards forming part of a working platform should be supported at each end by a putlog, and should not project more than 6 inches beyond it unless lapped by another board, which should rest partly on or over the same putlog and partly upon putlogs other than those upon which the supported board rests.

In such cases where the scaffold boards rest upon brackets, the foregoing suggestion should read as if the word bracket replaced the word putlog.

N. B.—Experiments have shown that a board with not more than a 6-inch projection over a putlog can be considered safe from trapping or tilting.

(5) All supports to centreing should be carried from a solid foundation.

(6) In places where the scaffolding has been sublet to a contractor, the employer should satisfy himself before allowing work to proceed thereon, that the foregoing suggestions have been complied with and that the material used in the construction of the scaffold is sound.

TESTS OF STRENGTH OF HOLLOW BUILDING BLOCKS.

At the present time interest is being attracted to the use of hollow blocks in place of solid brick in building construction. The advantages of these blocks are well known and some of them may be enumerated as follows: The principal advantage probably is in the saving of weight. In shipping this is of great importance, especially where the material must be sent long distances. In the walls themselves the saving of weight may often be of great importance as it lessens the loads on the other parts of the building and on the foundations. Another advantage is in the air spaces in the walls made by the hollow spaces which insure a drier wall. As regards the convenience in rapidity of laying the writer's impression is that the hollow blocks have the advantage in this, but he would request the opinions of others who have had experience along this line.

However hollow blocks are comparatively new in the construction of brick masonry and it often becomes difficult to secure their use. The principal objection which is raised to them is their lack of strength compared with solid brick This objection is so strongly urged that it furnishes a valid excuse for the presentation of a few tests which are to be described below. In the summer of 1901 the Grinell Opera House Co., of Grinnell, Ia., was considering the use of hollow bricks in the construction of their new opera house. Fearing that they were too weak for the purpose the company decided to have some tests made before deciding on their use. The specimens to be tested represented the product of the Mason City Brick & Tile Company, of Mason City, Ia., and were not selected by the company for the test. Instead they were taken at random from a pile of hollow blocks already delivered in Grinnell for the construction of another building. Hence they may be supposed to represent the average material that is actually used in building.

Four blocks were tested. Tests were made on the 100,000,lb. Riehle testing machine at the Iowa State College at Ames. The sizes of the blocks were respectively 4x8x12, 4x4x12 and 4x5x12. Two blocks 4x8x12 were tested. The 4x5x12 is an unusual size. These are the nominal dimensions in each case. Actual dimensions sometimes varied a quarter of an inch or a little more from those given. The results are indicated in the following table.

SIZE AND POSITION OF BLOCK.	TOTAL LOAD, LB.		TONS PER SQ. FT.	
	First Crack.	Crushed.	First crack.	Crushed
12x8x4-Flatwise	13,500	79,500	10.9	64.0
12x8x4-Edgewise	9,000	39,750	13.5	59.6
12x5x5-Flatwise	10,000	34,000	11.5	39.1
12x4x4-Flatwise	12,000	38,600	17.6	56.5

In all these tests the specimens were imbedded in plaster of Paris at the top and bottom which was allowed to set in 90 minutes. An adjustable top bearing was used to enable the machine to adjust itself to lack of parallelism of the top and bottom.

For comparison it may be said that architects allow

* A. Marston, in Brick.

5 to 10 tons per square foot pressure on brick masonry. This would give a larger factor of safety even in the case of walls built of hollow blocks. Of course in the wall built of hollow blocks piers of solid brick are usually built to carry concentrated loads from beams and trusses. It would take a solid wall of common brick about 80 feet high to give a pressure of five tons per sq. ft. from its own weight alone, and of course the walls of hollow blocks would have to be much higher than this before giving a weight of five tons per sq. ft., which our tests show would be only about one-tenth of the strength of the hollow block.

The writer has made a few other tests of hollow blocks which gave still stronger results than in these cases. It would therefore appear in general that hollow blocks should furnish a wall amply strong for the circumstances under which they are commonly used.

CONCRETE CONSTRUCTION IN BUILDING.

The Railroad Gazette prints the following particulars regarding the method and cost of concrete construction as employed in car shops at Elizabethport, N. J. :—

The concrete used in this work was in some cases made with an aggregate of engine cinders, in general with the porportion of 1 part of cement, 3 of Edison sand and 6 of cinders. Gravel aggregate was also used, composed of gravel as it came from the bank, mixed with sand and unscreened. About 1 per cent. was in cobble-stone two inches in diameter and over, the balance all sizes of gravel and sand to the smallest. When this was employed it was mixed with cement only, the amount of cement used being determined by experiment. In all cases the concrete was mixed very wet, so that no ramming was required. After being deposited it was puddled with a light wooden rammer to secure an even distribution. No attention was paid to the weather, concrete being mixed and deposited in any weather in which men could work.

When the temperature dropped below 25 degrees all water used was brought nearly to the boiling point and salted, using one pound of salt for 18 gallons of water. When the work stopped at night it was covered with canvas between the forms and sprinkled with salt. The forms for the work below ground were of rough hemlock; above ground, of yellow pine painted with soft soap, which gave a smooth surface. No provision was made for expansion and contraction from temperature changes with cinder concrete. This is good practice, but in gravel concrete a joint should be made about once in 150 feet. Some of the concrete was mixed by hand, some of it in mixing machines. Wherever the walls were less than 18 inches thick it was found that hand mixing was more economical, the labor cost for mixing and depositing the concrete being frequently as low as 50 cents per cubic yard. Where the machines were used the cost for mixing was reduced, but the cost for handling and depositing was so much increased as to over-balance it. In general, it may be said for building work that no machine mixer is economical that cannot be transported as easily as a wheelbarrow.

Facing putty may be prepared by mixing together equal parts of whiting and white lead and a small quantity of litharge, mixed together with boiled linseed oil. It is especially good for stopping small flaws in hardwoods.

BLISTERING OF PAINT.

A correspondent of the London Decorators' and Painter's Magazine gives the following causes and remedies :

1. Painting upon damp wood.

2. Using old paint which is fatty, which a lot of master painters do, telling the men to add some terebine to make same dry.

3. Having too much oil in the paint, and applying same too thickly.

4. Using too much driers, which causes the paint to dry on the top, forming a skin which, if followed up by other coats, dries in layers instead of forming one hard surface.

5. Boiled oil, I find, blisters sooner than raw, so I use it sparingly.

6. The painters do not use enough elbow grease in applying their paint, for I find in four cases in every six they apply too much paint on, instead of less and brushing it well out, which, if attended to, would make a better class of work.

7. The quality of materials.

8. I have also noticed several cases where fatty paint has been used. It blisters sooner on knotting than the other portions.

BUILDING WRECKING.

The building wrecking business is a comparatively new one in New York, and is the direct outgrowth of the extensive architectural improvements which have transformed the city of New York in the last two decades. When a piece of property is purchased now-a-days for the purpose of erecting on it a new business building or apartment house the owner is usually anxious to have the plot cleared for the builder, and in most instances even the foundations are taken out, so that new and more massive masonry may be constructed. It was the custom before the days of the wrecking concerns to give the builder the contract to take down the old structure on the site on which the new one was to be erected, and while some of the material was saved the greater part of it was carted away as fuel, junk or rubbish. The wrecking concerns to whom the demolition of buildings is now entrusted know the value of old building material, and usually find a market for the heaps of debris which look valueless to the layman.

"One must be an all-round mechanic, a builder, and a judge of values," said a man who makes his living by tearing down buildings, "to be a successful wrecker. It's nothing to pull down a house and save the big pieces, such as stone steps, sills and lintels, carved mantelpieces and inside fittings. That was enough in the days when there was no competition, but now-a-days we must save every foot of pipe, the ordinary woodwork, and even the nails out of the floors to get even on close bargains."

Much of the material which comes from the wrecked buildings is sold on the spot and carted away by the purchasers, but large quantities of all kinds of building material are stored in yards where they are easy of access when the customer who wants ready-made door-steps or well seasoned bricks may come to buy. Sheds are provided for the storage of doors, counters, wainscoting, window frames, flooring and trim, and racks and bins contain iron and lead pipe, gas and water fixtures, and nearly every item in the line of builders' hardware.

NOTE ON PORTLAND CEMENT MORTAR.*

By Charles P. Hogg, M.I.C.E

The object of this note is to draw the attention of engineers and others to the influence of the quality of the sand used in making Portland cement mortar. The subject was incidentally referred to in the paper on "Limes and Cements : their Nature and Properties," read by Mr. Alexander M'Ara, before this institution last session, in which he said, "As to the quality of sands, they are of very wide variety, so much so, that one part of an inferior, or soft clayey sand, will reduce the strength of mortar as much as three or four parts of clean, sharp, granite sand."

Engineers have devoted a great deal of care and attention to obtaining Portland cement of the very best quality, and of late years, fineness of grinding has been strongly insisted upon, in addition to the usual tensile test, it having been found that the fine granular residue had no cementitious value. There is no standard specification for Portland cement; but the following may be taken as a fair example of present-day practice : "The Portland cement shall be ground to such fineness that it will pass through a sieve of 2,500 meshes to the square inch, and that a residue of not more than 10 per cent. will remain in passing it through a sieve of 3,600 meshes to the square inch. Briquettes of neat cement, after being immersed in water for seven days, shall bear, without breaking, a tensile strain of 360lb. per square inch. The cement when made up neat, must not at any season of the year set in less than one hour."

In large contracts, it is usual to specify further, that the cement is to be emptied out on the wooden floor of a dry shed and turned over several times. This not only cools the cement, which is often delivered hot, but by air-slaking renders the free lime harmless.

If the cement is allowed to lie on the floor of the shed for several months, tests made from the exterior of the heap show a considerable decrease in the tensile strength of the cement, but those made from the interior of the heap generally show an increase. The results of a number of tests on this point show that the tensile strength of briquettes made from the exterior of the heap increase by nearly 300 lb. per square inch from seven up to 26 days, while the increase during the same period on briquettes, made from the interior of the heap, would probably not exceed 200 lb. per square inch.

What is known as the sand test is sometimes also specified in these terms : "The cement for testing is to be gauged with three times its weight of dry sand, which has passed through a sieve of 400 and has been retained upon one of 900 meshes to the square inch. The cement and sand having been well mixed dry, about 10 per cent. of their weight of water is to be added, and briquettes formed in moulds. The briquettes, having been kept in a damp atmosphere for 24 hours, are to be put into water, and to remain for 28 days, and they must then bear, without breaking, a tensile strain of 160 lb. per square inch."

The test for freedom from expansion, or contraction, is seldom specified, but it is important, and it is easily carried out by making two pats, 3 in. or 4 in. in diameter, on pieces of glass or slate. One of these should be placed in water, after it sets, and the other left in air. A good, sound, well matured cement should show no signs of cracking or lifting in either of the pats.

Now, while engineers have taken all these elaborate precautions to obtain Portland cement of the very best quality, they have, generally, been content to specify simply that the sand shall be "clean and sharp," and the consequence is that, in many cases, sand is used for Portland cement mortar which reduces the strength of the mortar to a much greater extent than the amount of sand added would lead one to expect.

The sand test is supposed to be carried out with sand of standard quality, but where is such a sand to be obtained? In practice the question resolves itself into the cement manufacturer supplying the very best and sharpest of sand he can possibly procure. There is always the difficulty of obtaining a standard sand, and there is, further, the objection that tests made with a standard or normal sand give no indication of the strength of the mortar obtained with the sand in use on the work under construction. The general consensus of opinion is to the effect that the finer the cement is ground the stronger will the mortar be with any given quality of sand; but if a soft, impure sand be used, the advantage of fine grinding would have been far better spent in obtaining cleaner sand or in washing and cleaning the impure sand. Both mud and shale are highly objectionable in sand for cement mortar. The precentage of mud in any sand may be obtained approximately by placing a quantity of the sand in a cylindrical glass vessel containing water, shaking the contents together a little, and then allowing the materials to settle. The particles of sand go down at once, and the fine mud in suspension in the water settles finally on the top of the sand.

The importance of using really good sand for Portland cement mortar is so great, that the author is inclined to advocate the adoption of the sand test rather as a test of the quality of the sand than the cement. Taking the tensile strength of the neat cement as a standard, he would reject any sand which reduced that strength beyond a given percentage.

Taking the qualities of the various sands into account, tests lead to the following conclusions as regards cement mortar : (1) That sand containing particles of shale should be avoided as far as possible, more especially if the shale is inflammable. (2) That, generally, coarse sharp sand is to be preferred to soft fine sand. (3) That sand containing any trace of clay, mud, or earthy matter should be washed before being used. (4) That sandstone shiver sand is as good as the best sand.

* From Transactions of the Institution of Engineers and Shipbuilders, Scotland.

TREATING MARBLE.

Compare a slab of marble, hand polished, with one that has been polished by machinery, says Mr. Halsey Ricardo. In the first instance, the surface is full of life and movement ; the light falls on its tiny depressions and irregularities, awakening wayward reflections strengthening and palliating its colors, developing its lustres and translucencies, so that it becomes rich in story as well as in hue. In the other there is the dead level of polished surface, unassailably perfect, but, comparatively speaking, uninteresting. The life and vivacity of the marble are gone ; it is merely a polished record, with the pleasant part of its individuality rubbed away into a wearisome uniformity.

CRUSHING BLAST FURNACE SLAG.

An important industry has grown up in the Schuylkill Valley region of Pennsylvania in crushing the slag found in the huge cinder banks surrounding the blast furnaces. This material is crushed to all sizes, and is used for roofing, concrete, macadamizing and the manufacture of patent stone. The demand for it has steadily increased and it is being shipped to points as far east as Boston, and as far south as New Orleans. One or two large cinder banks have already been exhausted, but there still remain many millions of tons. There are large crushing plants now established at Leesport, Moselem, Mt. Laurel, and at Bechtelsville. It is declared that only the slag produced years ago is of value, as the recent output of the furnaces is worthless for these purposes.

LOADS ON FOUNDATIONS.

The following are the safe loads recognised by the New York Building Code:—"Soft clay, one ton per square foot; ordinary clay and sand together, in layers, wet and springy, two tons per square foot; loam, clay or fine sand, firm and dry, three tons per square foot; very firm, coarse sand, stiff gravel or hard clay, four tons per square foot, or as otherwise determined by the Commissioner of Buildings having jurisdiction." In Chicago the highest load recognised is 4,500 lbs. per square foot. It is necessary therefore to devise remarkable methods to overcome the shortcomings of the natural foundations. The expense which is sometimes inevitable is exemplified by a building in San Francisco which is 75 feet square. Below the surface of the site, at a depth of 25 feet, is a concrete platform 96 feet by 100 feet, and 2 feet thick. On this is a layer of 15-inch rolled girders, making a continuous beam 96 feet long; above are alternate layers of concrete and girders, and the area thus constructed is 70 per cent. greater than the actual floor area of the building. By this costly arrangement it is calculated the pressure on the earth's surface will not exceed 4,500 lbs. per square foot.

AN INSTRUMENT FOR DETERMINING THE HARDNESS OF WOODS.

In every description of wood, by a practical man, says Mr. Herbert Stone, in a paper read before the Society of Arts, the elements of weight, hardness and colour are considered. Sometimes the weight per cubic feet is given, and the colour, apart from its fluctuations, is often accurately pictured, but the hardness is a quality which is practically left to our imagination. I have been so much impressed with the necessity of some means of measuring the degree of hardness that I have constructed an instrument which is capable of giving a fairly accurate reading of the resistance to impact of a wood (not of its hardness pure and simple, because the resistance to impact is made up of elasticity plus hardness), but it is a fair parallel to the impression of that which we call the hardness makes upon our sense of touch. I will not weary you with a description of this contrivance, but will merely mention that the principle is as follows: A steel ball of a known weight falling a definite distance upon a surface at an angle of half a right angle will fly off in a horizontal direction, and describe a curve or trajectory which will be longer or shorter according to the amount of force absorbed by the wood. A self-recording arrangement and all necessary adjustments are attached to the machine. The hard and soft zones of a wood give different readings, so that a number of trials have to be made and an average struck. I take the average of ten trials, displacing the wood five millimetres between each.

ANCIENT METHODS OF FLOORING.

Before Portland cement and concrete were introduced, builders had recourse to some strange expedients for flooring, says the London Builder's Reporter. Sir Hugh Plat maintained that ox blood and fine clay tempered made the best floor in the world, end that this mixture laid in any floor or wall formed a very strong and binding material. The usual method for earthen floors was to take two-thirds of lime and one of coal ashes well sifted with a small quantity of loamy clay, to mix the whole and temper it well with water. The stuff was allowed to lie in a heap for eight or ten days. This process was repeated at intervals until it became smooth, yielding, tough and gluey. The stuff was then laid to a depth of about 3 inches thick, during the hot season for preference and smoothed with a towel. Floors of that kind were in favour for malthouses. If cheapness was required coarser materials were used. For better-class floors, in addition to the preceding mixture, a further mortar coating was laid down to a depth of half an inch. This consisted of lime made of rag stones, tempered with a little white of eggs, the more eggs the better, to a very high pitch. It was necessary that the second layer should be laid down before the under-flooring was too dry, so as to insure their incorporation. If the flooring was rubbed with oil it was supposed to assume a polish which gratified the eyes of housewives.

BUILDING LEGENDS AND CURIOSITIES.

There is much that is curious and legendary associated with the matter-of-fact art of building. Thus, it has been written of the spire of Chesterfield Church—which many consider wonderful, though, as a fact, it is only somewhat out of the perpendicular—

Poor devil! poor spite,
To make a spire a laughing-sight.

This rhyme refers to the perversity of the builder, who originally erected the church without a spire, but, being compelled to add one, made it crooked. One of the legends attributes the mischief to the Prince of Darkness, who one day, being fatigued, folded his wings and rested on the steeple. Some of the incense which was being wafted in the aisles below escaped from the church, crept up the steeple, and tickled the archfiends' nose to such purpose that he gave a terrific sneeze and so dislocated the steeple that it has been twisted ever since! Another tale in connection with this church is that on the occasion of a wedding party passing into the building the steeple bowed to the bride and bridegroom and has remained crooked ever since. The same tradition attaches to an old church at Lancashire, of which it is said:—

The church at Little Winwick,
It stands upon a sod;
And when a maid gets married there
The steeple gives a nod.

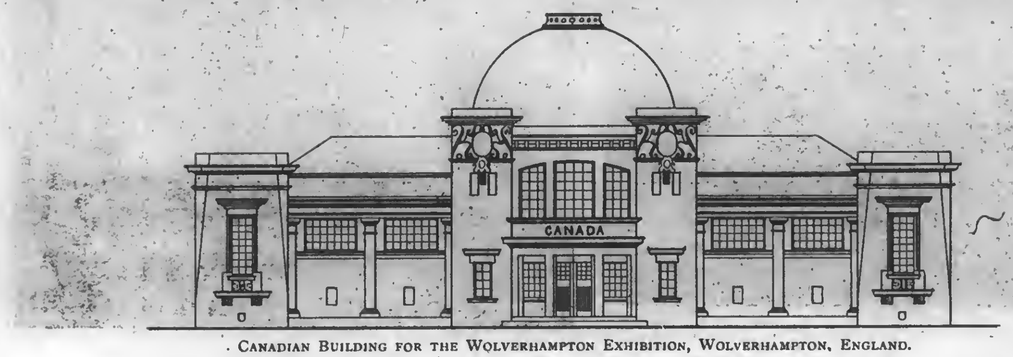
Alas! how many ages
Their rapid flight have flown,
Since on that high and lofty spire
There's moved a single stone.

THE PARK AVENUE HOTEL FIRE.

To the Editor of the CANADIAN ARCHITECT AND BUILDER:

Sir,—It pertains to you, through the columns of your now widely circulated journal—to you, say, the exponent of architectural requirement in Canada or elsewhere to abet me in endeavoring to obtain such compulsory legislation as will put an end to these ever-recurring fatalities.

I petitioned the U.S. government and that of Canada in January, 1901, to do the needful, when they both replied that it pertains to the several states of the union, and to the several provinces to legislate on such matters; while the requirement being the same it would be so much more simple and expedient for the central government to enact a law for the purpose.



CANADIAN BUILDING FOR THE WOLVERHAMPTON EXHIBITION, WOLVERHAMPTON, ENGLAND.

The architect has solved his share of the problem, it pertains now to the government to enact under penalty that what is suggested be carried out.

The system was exhibited in Paris in 1900 and reproduced by the Scientific Journals of that city which admitted it to be as set forth in the heading to the exhibit, the only sure, simultaneous and instantaneous mode of escape from the upper floors, dormitories, etc., of convents, colleges, hospitals, lunatic and other asylums, hotels, theatres, etc., for old or infirm men and women, children, the sick, the demented. By means of a walled-in stairway to reach and enter which one must go out on to a balcony communicating therewith. At foot of stairway, a fire-proof corridor reaching through the building to an exit at street level. The stairway situated at rear of building so as not to enroach on more valuable space on the street front, and the corridor raised over head or to the ceiling of the ground floor or story, that is the principal floor or "Rez de-chaussee" so called by the French; in a way that it may be passed under so as to interfere in no manner with the interior economy of the building, or circulation of the public on said floor.

CHAS. BAILLARGE,
Quebec, March 3rd, 1902. Architect and Engineer.

FIRE-PROOFING MATERIALS AND METHODS.

Mr. Edward Atkinson, the well-known insurance expert of Boston, has addressed to the Manufacturers' Mutual Life Insurance Co., the following:

A few months since, before my recent visit to England, I made an effort to secure materials and contributions for a thorough test of so-called fire-proofing materials, floors and the like, mainly devised for the protection of steel from heat. This effort was not sustained to any considerable extent by the promoters of various types of construction nor by the makers of concrete. I therefore dropped the subject for the time.

On my recent visit to London, in consultation with the architects and engineers who constitute the British Fire Prevention Association, I was confirmed in my distrust of some of the materials which have been commended for the protection of iron and steel used in construction. The attention of that Association is mainly given to what is called "fireproof construction," not only in city buildings but in factories and workshops as well.

Our attention has been mainly given to the slow burning construction of brick and timber, and we have not yet been called upon to deal in any large way with steel construction. In anticipation of such demand upon us it is necessary for us to know the present state of the art.

In Great Britain it is said to have been proved that many of the concretes, some of which are there called "breeze," of which coal ashes are the principal component material, are very destructive to iron and steel. These ashes come from coals containing a good deal of material which may cause corrosion, and the long-continued contact even of dry ashes with iron and steel beams, wire or thin plates, imbedded in them, is said to oxidise them. This may come however from the avidity with which ashes absorb humidity from the atmosphere and may be attributed to that rather than to any other fault in the ashes.

Any concrete or any material containing plaster of Paris (sulphate of lime) is known to be somewhat dangerous if not destructive, and there may be other causes of corrosion as yet unknown to us. We know of some cases in which corrosion has set in very rapidly on gas pipes and on cribs of rails intended for foundations, owing to corrosive qualities in the concrete in which they were imbedded. We are aware that many investigations and reports have been made by the representatives of special methods, but we are not informed of any general report or conduct of tests corresponding to those now being made by the architects and engineers who have organized the Fire Prevention Association of Great Britain. We therefore address the following questions to you:—

1st. What attention have you yet given to causes of corrosion other than ordinary humidity which may get through minute cracks in any kind of veneer or covering for steel members? In other words, what causes of corrosion have been developed in your practice other than those arising from dampness?

2nd. What precautions have been taken to meet this hazard?

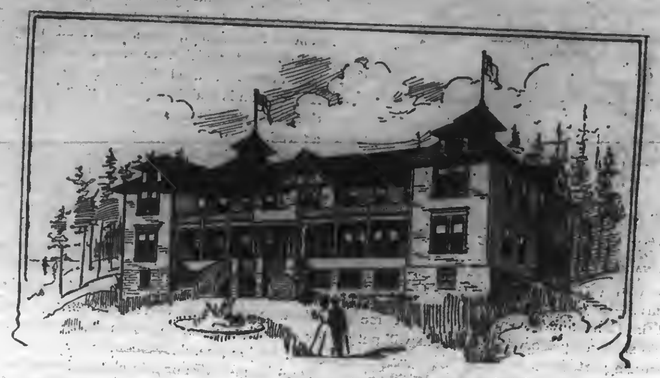
3rd. What general or special information has been printed upon this subject? Who are the authorities and what printed material can be found and where?

4th. What studies are you yourselves making in this matter?

5th. What knowledge have you of active corrosion from dry materials coming in contact with the iron or steel frames, posts, or other members of any building, or iron used in foundations?

6th. To what extent do you depend, if at all, upon angle irons, wire or sheet metal imbedded in concretes for floors or arches, for the stability of the floor after the cement or concrete has become permanently set?

I have asked these questions with the intention of making arrangements for an exhaustive study of this subject and for such tests as may be possible of each and all the various coverings now upon the market for protecting iron and steel; the concretes, the fireproof floors, and all other matters in which corrosion from any cause may be a source of danger."



FREE HOSPITAL AND COTTAGES IN CONNECTION WITH THE SANITARIUM FOR CONSUMPTIVES AT GRAVENHURST, ONT.

APPORTIONING THE COST OF PERMANENT PAVEMENTS.

Alderman Crane, of the Toronto City Council, has given notice of his intention to move that the city engineer be instructed to report to the Council the class of pavements which he considers (taking into consideration the locality where the same is laid) to be permanent pavements, and that the Council determine the class of pavements which shall be deemed permanent, and that thereafter the local improvement or other by-laws affecting the same be amended so as to provide that where a permanent pavement is once laid as a local improvement, the same shall be kept in perpetual repair out of the general funds of the city. This action on the part of Alderman Crane is in the right direction. The local improvement system, as it at present exists, is, in some respects, very unfair to property owners. The persons who are most benefitted by permanent pavements are owners of departmental and other stores who use a large number of vehicles for the delivery of their goods. These companies effect a large saving yearly in horses and vehicles by reason of the improved pavements which have been put down in recent years, the cost of which has been charged, to a large extent, against the property owners on the various streets. We refer now more particularly to the residential streets where, it is safe to say, the pavement is least used by the owners of the property fronting on the street. This being the case, it is manifestly unfair that that the property owners should be called on to bear so large a proportion of the cost of improved pavements. While it is no doubt true that the value of property is, to some extent, enhanced by the putting down of good pavements, it is also true that increased assessment invariably follows, so that the net advantage is small. A larger proportion of the cost of such pavements should in future be borne by the taypayers as a whole, while if means can be found of placing a considerably increased assessment for this purpose on the shoulders of the owners of delivery wagons, it ought to be done.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 15th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

NOTES.

Mr. O. G. Carscallen, Vice-President of the Gurney Tilden Company, of Hamilton, was recently presented by the travellers of the company with a gold-headed cane.

Professor Galbraith, Principal of the School of Practical Science, Toronto, was the guest of honor at a dinner held on Feb. 28th by the S. P. S. graduates resident in Pittsburg.

The outcome of a lawsuit at Cleveland over a party wall dispute, has led to the giving of positive orders to the city engineering and building departments, to carefully survey property on which business buildings are to be erected in future and establish beyond question the lines of the lot or plot of ground on which such improvements are to be made. This will prevent a repetition of this case. Other large cities might profit by Cleveland's experience.

Analysis of the incrustations taken from the Portland stone balustrade round the base of the dome of St. Paul's Cathedral, shows them to be composed chiefly of hydrated sulphate of lime associated with some siliceous matter and minute particles of carbon in the form of soot. The solvent action exerted by rain charged with sulphurous and sulphuric acid derived from the gases and smoke of innumerable chimneys of the surrounding buildings, has, after the lapse of two centuries, transformed the original carbonate of lime of the Portland stone into sulphate of lime, which in a more or less soluble condition has been carried by water action and gradually deposited as calcareous tufa or stalagmite on the underside of the coping-stone.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

Builders' Conventions.

THE National Association of Master Builders of the United States held an informal meeting in Washington on March 5th to arrange the preliminaries for a regular convention to be held in the same city next October. Three years have passed since the last general convention of the Association. The value of such gatherings is recognized as affording opportunity for considering all important questions affecting the building industry. An occasional convention of the master builders in the various provinces of the Dominion would no doubt prove beneficial to all concerned. Apart from local Builders' Exchanges in a few cities there exists no organization in Canada among employers in the building trades.

City Improvement.

ON the 23rd inst. an influential deputation will wait on the Board of Control of the Toronto City Council, to urge that a sum of money be appropriated sufficient to cover the cost of a report and plans by an expert for the future improvement of the city. It is understood that private subscriptions have been offered for this purpose on condition that the City Council will make an appropriation. It is certainly time that action should be taken in the direction of working out the improvement of the city on definite lines instead of piecemeal, as in the past. This should be done in the best possible manner under the direction of an expert of wide experience. The plan should include not only the city proper but the outlying parks. The cost of a preliminary report and plan should not be very large, and the working out of the scheme could then be proceeded with year by year. It is hoped that the Council will be as much alive to the future welfare of the city as are the public spirited citizens who are moving in the matter.

Some Lessons from New South Wales.

A gentleman who recently spent some time in visiting Canada after having lived many years in New South Wales, has some interesting things to say about that country. He describes it as a country of vast natural wealth. As evidence of its development mentions that, although the population is only 800,000, the export trade amounts to £13,000,000 annually. He states that New South Wales appears to be the Mecca towards which political theorists and economists tend, and in consequence socialistic ideas prevail to a much larger degree than in Canada. For example, all railways, telegraph lines, and public works of every kind are managed directly by the government. Asked regarding the result of these conditions, his reply was that under the prevailing system the cost of public

works is very much greater than would be the case under our system of constructing such works by contract. Another deplorable result is that bribery and corruption universally prevail, and the standard of public morality has become sadly impaired. Some years ago the government of New South Wales borrowed a large sum of money for the purpose of constructing a railway from one end of the country to the other, a distance of about 1,000 miles. This money, however, was never used for the purpose for which it was borrowed, but has been diverted and frittered away on a great number of minor objects. Much of it no doubt has found its way into the pockets of the politicians. There is here food for reflection for the press of this country and those who are clamouring for the control by the government and the municipalities of all kinds of business enterprises.

Bricklaying in England and America.

Much interest has been awakened among architects, builders and building workmen in England by the results achieved by the contractors in the construction of the British Westinghouse Electric & Manufacturrng Company's works at Manchester. The contractors are an American firm, Messrs James Stewart & Company, of St. Louis, Mo. Previous to the commencement of work on this factory, the average number of bricks laid per day by Union workmen in England was about 450. In a letter to the "London Times" Mr. Stewart states that the average attained under the direction of his superintendent on the Westinghouse Company's buildings has been from 1,400 to 1,800 bricks per man per day of nine hours. The averages mentioned included face brick work. On common work an average of 2,250 bricks per man per day was reached. The walls range in thickness from 19 to 23 inches. The bricks were laid in mortar. In the construction of a chimney stack at Birkenhead, by the same contractors, an average was attained of 1,976 bricks per man per day of nine hours. Mr. Stewart states that the results achieved in the last mentioned case were in part attributable to the facilities afforded the workmen, such as a double platform lift, each platform holding two barrows of bricks, one ascending the other descending. Only fifteen seconds was occupied in raising this platform to a height of 150 feet. Soft mortar was used instead of the stiff mortar usually employed in England, thus permiting enough mortar to be laid with one stretch of the trowel for half a dozen to a dozen bricks, and allowing of the bricks being laid by a light pressure of the hand and a light tap of the trowel instead of by repeated hammering of the trowel to force the brick into place as in stiff mortar. As an incentive to the workmen, they were paid 1½d per hour above the Trade Union rate. A record was kept of each man's work and the workman who failed to measure up to the standard were dispensed with. The new standard for workmen which has thus been established by American contractors should result to the advantage of English employers and prove a hard blow to the efforts of the Unions to restrict, to the greatest possible extent, as in the past, the amount of work which Union men shall perform. Mr. Stewart states that in the United States the workman's average per day is from 2,000 on the best class work, such as private residences, including face brick as well as common, to 2,500 and even 2,700 including face and common on other structures. This is far above the Canadian standard. The average here is from 700 to 1,000 bricks per day according to the character of the work.

Justice to Tenderers

The final action of the City Council of Toronto, with regard to awarding contracts for concrete sidewalks, tenders for which were received recently, is being looked for with much interest. When the tenders were opened, it was found that a firm of Chicago contractors had put in the lowest bids for the bulk of the work, and the Board of Control recommended that the contracts be awarded to them. Immediately that this decision was announced, the alderman were besieged by local contractors, and the cry was raised that the successful tenderers should not be given the work because they were aliens. This objection having come to the ears of the Chicago firm, they sent a letter to the city authorities expressing their willingness to open an office in Canada, and to employ none but Canadians and Canadian material in the carrying out of the work. To our mind, this offer removed every legitimate ground of objection, and should have secured them the contracts. Such, however, has not so far been the result. The local contractors have organized and are evidently bringing to bear as much pressure as possible to compel the aldermen to withhold the contracts from the lowest bidders. It is to be hoped that a majority of the members of the Council will act justly in this matter. The local contractors are not entitled to these contracts, first, because their tenders were not the lowest submitted, and second, because they are suspected of having agreed together to extort from the city an exorbitant price for the work. If the Council violate the principle of giving contracts to the lowest tenderer, where the securities and all other conditions have been complied with, they will justly be accused of sacrificing the interests of the tax-payers and of dealing unjustly by outside contractors. The result will be that in future no outside bids will be submitted for the work in Toronto, and the local contractors will be in a position to charge what they please. The Council should either cease to publicly advertise for tenders, and let it be known that no outsider need apply, or stand by the principle of giving contracts to the lowest bidder whether he be an insider or an outsider. Since the above was put in type the contracts have been given to the City Engineer.

THE BEAUTIFYING OF CITIES.

The Park Committee of the City of Sherbrooke, P. Q., have arranged with Frederick G. Todd, Landscape Architect, of Montreal, to prepare plans for their various parks and squares. Mr. Todd's contract covers five years and, aside from planning for the parks, he will make a report each year dealing with the growth and extension of the city, which will take up its future needs as regards the location of public buildings and streets and the beautifying of the city.

The City of Sherbrooke is specially fortunate in having set aside an unusually large amount of land for parks and playgrounds, the area, according to the 1901 Park census, being greater in proportion to the number of inhabitants than any other city with the exception of two or three in the United States. It is a matter for congratulation also that the City Council have decided thus early to have a general scheme definitely laid down which can be followed from year to year.

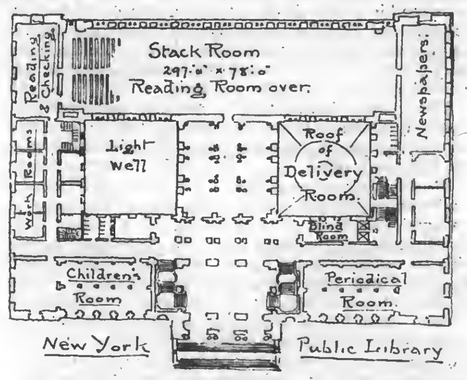
LIBRARY DESIGN.

In former days a library was essentially a place where books were kept; now it is essentially a place for giving out books. The value of the volume was the original motive for building; the value of its contents is the motive now. So that a library has become a place where books are stored, safely of course, but for the main purpose of distribution on as large a scale as possible; and the leading idea is how to get the books into the hands of the reading public. Librarians are not even content with this, but want to enlarge the limits of the reading public and create a reading public of a better kind, by taking the younger generation in hand and inducing them to read good books.

This being the case the commercial analogy has impressed itself upon library methods. Librarians trying to reach the public take a hint where they can from the shopkeeper. Books on China were rushed to the front in Toronto Public Library long before the allied forces reached Pekin. A special Prohibition catalogue is out now, to educate the voter for the coming struggle. Slips with a list of the better books of a kind are prepared in some libraries as book marks to entice the reader, especially the young reader, from his affection for the worse.

Along with these small arts of reaching the public the great schemes have been considered, and are to some extent adopted. The late Dr. Poole of Chicago had the Newbery Reference Library built somewhat on the system of a departmental store; each department of literature in a room by itself; so that instead of conveying books from a far distant depository to the reader in a general reading room, the student can go to the department in which his researches are being made and take down for himself the books he wants. This is certainly a great idea and should be, in the case it suits, a complete success. But there must be many cases for which the system creates difficulty for the reader. A reference library is the very place where one wants to be in contact with two or three departments at once. An historical work on the first floor is likely to require for its elucidation a map from the map room in the attic and an article from the periodical room on the ground floor. It seems in fact as if this system could be applied more practically to the lending department, so as to avoid procuring books from the stack rooms by a machinery of pneumatic tubes, automatic lifts and electric railways, upon which a planner pounces at once as an indication of something wrong in the plan. A borrower wants but one book; or, if he wants more than one, he wants them to take away with him; and there is no reason why he should not go from the department of fiction to that of science or elsewhere and pick up his books as he would his purchases in a departmental store. The department rooms in different stories could back upon departments of the many-storied stack room so as to bring the attendants into close contact with both the books and public; or even, if it is desired, continue into the middle class of libraries the system of open access to the shelves which is now so much in vogue in libraries of the smallest class. But open access is still on its trial. The public seems to be "indifferent honest;" and there are other difficulties, which increase with the size of the library; so that there is no question at present of open access except in small libraries.

The large public library would require a series of articles to itself. Both the public department and the working department are multifarious and tend to increase. On the one hand the library may combine, with its book departments, galleries for the display of pictures, prints, photographs, rare books and other educative objects, besides rooms for special studies, which require not only books of reference, but such additional circumstances as a table for drawing instruments, space to spread out specimens from a hortus siccus, or quiet to use a microscope. On the other hand, behind the scenes, the ordinary works of receiving, preparing, cataloguing and checking the books may be supplemented by printing and binding shops, arrangements for dealing with branch libraries, etc. These are the variations that occur in any problem and for them the architect must be briefed. It would take too much space to study now these minor circumstances, but the essential conditions of the problem may be summarized, as they appear in the plan for the New York Public Library; a plan so well considered and carried out that it may be taken to represent the best that is known on the subject at present.



The stack room runs across the back end of the building, sideways on; so that it may be duplicated without carrying the ultimate limits of the stack room further away from the delivery desk than is the case in Boston now. In this position also the stack room is in contact with the main building all along its length, and comes into close communication with numerous minor reading rooms. The main reading room, for 800 readers, is on top of the stacks. This is the proper place for it, not as in Boston in front of the building, with the halls between it and the stack room. Placed over the stacks, very simple arrangements suffice for communication and the delivery of books; and there are additional advantages in the way of quiet, of light and air, and of construction. There being nothing above there is no need for columns, which are not impressive when dotted over an area of this kind. The 78 feet span may be roofed over clear and make a noble feature. Finally there is the principal advantage, that the reading room can grow as the stack room grows; for, when the stack room is repeated, the reading room can be repeated too.

The other great points in this plan are that the book borrowers—the people who merely come and go—are kept away in a place by themselves; a large room, convenient for the borrowers and in close connection with the stacks, but in the basement with a side entrance peculiar to itself. The rest of the floating population are confined to the ground floor; the periodical and newspaper readers are on one side and the children on the other, as near as possible to the entrance. Thus quiet is secured for the rest of the library.

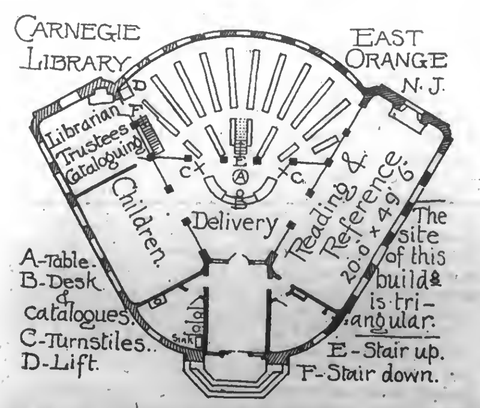
There is an undetermined middle ground between the large library and that which may be classed as

small. The essential distinction which lifts this division above the small library class is the extension beyond the power of control by a central office. Detailed supervision passes from the hands of the librarian into that of a staff; and the librarian's office, instead of being the first thing to meet the eye, should be, though accessible, retired. In other words the library has reached the sub-divided stage and sub-division—the unified sub-division which keeps all purposes apart but all in touch with the books—is the main thing to be brought about. The borrowers should be kept as far as possible from the readers; the children from the grown-up readers; and the newspaper readers from both. In short the principles illustrated by the plan of the New York library may be applied on a much smaller scale, as long as there are similar combinations of purpose.

The small library has more direct poetry than any, and is an attractive problem. But its basis is severely practical. The poetry consists in the building's unity, and therein lies also the practical basis. A librarian with one or two assistants must attend to everything and oversee everything. Hence the public functions must be all on one floor and as far as possible all in sight from the administrative centre. This will make smooth the path of the librarian. It is necessary also to make his paths short. A few unnecessary feet to be traversed, coming and going all day everyday, mount up in the aggregate to a great deal of unnecessary work; and the more easily the librarian can do his work the better the public is served.

The problem is therefore to arrange space for purposes of different kinds, all so separated as to avoid mutual annoyance, yet all in close communication with the librarian's office.

It would be well to assume a fair standard of accommodation for the present purpose, taking the stage of library development suitable for a small town. It is for libraries of this kind that Mr. Carnegie's recent gifts to towns in this country will be chiefly applied. We may then perhaps assume not less than: 1. For the public; a reading room for the grown up people, a reading room for children, and ample space apart from these for the coming and going of borrowers. 2. For the librarian; a delivery desk and a private room in connection with it; for talking is not the thing in a library, and if the librarian wants to talk at length he should have a place for seclusion, for the sake of the public as well as for the sake of privacy. There should be also working room for unpacking, marking and cataloguing the books. The unpacking room would be best in the basement, but the other work should be done on the ground floor, in close connection with the librarian's office. 3. For the storage of books; plenty of room now and an opportunity to grow.



The last sub-division is the most difficult part of the library plan on account of the continual increase of the number of books. The difficulty is complicated by the present manner of admitting the public to the bookshelves. If the librarian is to keep an eye upon the stacks where the public are handling the books, undoubtedly the circular stack room with radiating stacks is the best. If future extension of the stack room is to be considered, undoubtedly the circular form is not the best. One is inclined to think that there is too much stress laid upon the need of making a sort of policeman of the librarian. There is a New York story of a man who came down Broadway, under an umbrella, in a heavy shower. The doors on both sides of the street were full of people taking shelter; people who had not umbrellas and wanted them. The man lowered his umbrella at a shop door, looked round upon the assembled multitudes, stood up his umbrella against the wall and went in. The public will police each other if there are enough of them. There is also such a thing as creating a sentiment of honour by assuming it—judiciously. To some minds it might become a sort of sport to circumvent a fussy librarian by irregular borrowing; whereas if this were assumed to be (as it is) an act of public dishonor too mean to be thought of in connection with respectable people it would cease to be a temptation. There will always be a sprinkling of the naturally bad; but the best means of throwing difficulties in their way is to tone up the rest.

The librarian's principal business is to help the public to get the books they want or ought to have; and the principal need in the book room is plenty of space for the needs of this generation and a chance for the next to enlarge it if they want to.

The most obvious arrangement of these functions is to place the book room and working offices in the rear, the reading rooms and delivery hall in front and the librarian between. The delivery hall and desk will come naturally in the middle and the reading rooms on each side. Fortunately the reading room for grown up people is usually required to be of a larger size than that for children so that it is not necessary to make the front part of the building symmetrical in plan. In a building of such small size and so few parts, symmetry is difficult to manage without producing a dull exterior effect. If there are supplementary public rooms on an upper floor to be approached, the clear sweep of rooms on the ground floor is most easily preserved by throwing the staircase to the front, where t will be of great service in establishing an unsymmetrical balance of parts.

Inside there is room for a large effect. It has been urged that, for the purpose of keeping all parts in view from the delivery desk, the library should consist f an area under a single roof; subdivided, on the floor only, by desks, seats, bookcases and balustrades. Fortunately this expedient would not so well serve the end in view as a more architectonic method. It is the floor that is to be kept clear not the ceiling. The continuous ceiling would be a great sound carrier and is better broken. For architectonic purposes also—to give a sense of seclusion in the various rooms—it will be necessary to sub-divide the ceiling; for the eye measures a room by the ceiling rather than by the floor. If therefore the rooms are divided from the hall by an open screen of columns, there will be a satisfactory sense of seclusion in the reading rooms; while the eye can range the whole length of the library, with a sense of space increased by the intervention of columns; and everything will be in sight from the delivery desk. Columns are a slight obstruction to a person immoveably seated in a pew at church, but none at all to one moving about; and the delivery desk has usually a bowed front to give it greater extension into the hall.

It is not possible in a short space to enter further into the question of plan, much less to discuss matters of detail; high light in the reading rooms, artificial ventilation screened from dust, washable floors, the make and dimensions of book cases, etc.

The present article is only an attempt to appreciate the situation as a help to imagination in planning.

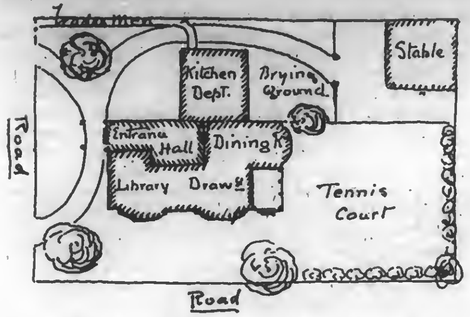
W. A. LANGTON.

CITY PLANNING.

LECTURE BY W. A. LANGTON, PRESIDENT ONTARIO ASSOCIATION OF ARCHITECTS, BEFORE THE CENTRAL ONTARIO SCHOOL OF ART, MARCH 20TH, 1902.

I want to begin at the very first principles and find out what it is that makes a city beautiful; for if you fill a city with statues and fountains, you have but filled it with beautiful objects. What we want to do is to make the city itself beautiful.

At the bottom of everything that is beautiful, there is a plan. Every good thing that is made, is made according to a plan: a house, a piece of furniture, a piece of machinery.



I have placed upon the board an illustration of this. I am not going to talk to you about house planning, but this is something that we will all understand which will show the nature of planning, and I have therefore put upon the board the design of a house for a country town, on half an acre. The first essential in making a good plan is that the house shall be divided into its several departments in such a way that they do not clash with one another. On this design the family living rooms are colored blue, the kitchen department is colored yellow, and the public part of the house — the entrance, staircase and hall—are colored red. I wish you to notice that they are all contained in themselves, that there is no blue in the red, and no yellow in the blue; that there is no conflict. The kitchen department has to do with the dining-room, and therefore the living rooms touch the kitchen department at this point. The kitchen department also overlaps the public portion just at one point by which it gets communication with the front door. The public touch the kitchen only at the front door; they touch the other living rooms. This principle extends not only to the departments of the house, but also to all the departments of the grounds.

The service department outside does not touch the living part. As the north side of the house is given up to the service department, the north side of the lot is given up to the stable and yards. The drive from the stable runs along the north and meets the public drive at the entrance on the north-west. Thus, just as the living rooms of the house occupy all the south and eastern sides, all the ground to the south and east is private, not intruded upon by either service or the public.

When this design was received, the owner had only one suggestion to make. He thought the stable ought to be placed in the south east corner. See how this upsets everything! The stable drive must run all round the south side in front of the living room windows. The tennis lawn can only exist by being shoved up by the drying ground. The man, when he goes from the stable to the kitchen must either cross the tennis lawn or go round by the drive past the drawing room windows and the front door.

That explains the nature of a plan.

The first consideration in making a good house plan then, is that the functions should be kept together. In the same way, the first thing that we have to consider in planning a city, if we have the opportunity of planning it from the bottom, is to keep all the functions together. It is not so difficult to do this after a city is started as you would think, because to a great extent functions do keep together. There are cities now which are almost perfect in this respect.

In Boston, when they laid out the Back Bay—I fancy everybody knows something about the plan of Boston: there was the old city surrounded by a low, marshy district, and beyond that the beautiful suburbs. They have filled in the marshy district (the Back Bay), and made it the principal residential part of the city. In so doing they made Commonwealth Avenue, a long wide avenue with rows of trees, which goes through the Back Bay and connects Boston Common, the edge of the city, with the suburbs, so that the rich man who lives in the suburbs, which are as beautiful as any suburbs in the world, can come to the city and go back every day and need never in the whole course of his existence, unless he wants to, see anything squalid. He can drive along treed avenues all the way to his office, and so all the way back again. His church is on that line. His office, if he has an office, and the principal shops which he will frequent will be within a stone's throw of Boston Common. His Club faces it.

In the old part of the city there is another story. Here you have shipping, warehouses and smells. Here also the poor and disreputable people live. And instead of the spick and span appearance of the elegant part of Boston, you will find streets covered with paper as ours are with maple leaves in November.

That is an illustration of how a city can, subsequently to its first planning, be made or arranged so that the functions, the different parts of the city, keep each to itself.

In Berlin there is a law which divides the city into districts, and does not allow any conflict in the districts. It is not lawful to put up a tall apartment house in the middle of the villa district. Liberty, after all, is relative. A man cannot do what he likes in every case. One ought not to learn the cornet in a lighthouse. And a first principle of city life is that a man cannot do what he likes with his own. If any one doubts that, let him try to start a glue factory on King Street, between Yonge and Bay Streets, and see what happens.

It is only necessary to extend that principle in practice to find that we restrict to a great extent the building and other arrangements in different parts of the city. I have here an extract from a By-law which was passed in Rochester, in 1899-1900, which says: "It is inequitable as often happens to sections of our city which have received a trade mark of special value by reason of residential unity and beauty to have some vandal destroy such special value on the plea that "'he has a right to do what he likes with his own property.'" They passed that by-law and decided for Rochester that a man has not a right to do what he likes with his own property. That is the first foundation of municipal planning and municipal intervention in making a city beautiful, that a city has got something to say as to what is to be put up in the different parts of the city.

It seems to me that one of the first considerations for a beautiful city is that there should not be such a mixture of business as we have got in Toronto. Factories should be in an outlying part of the city, and the offices and residences should be in touch with one another.

Why should a factory be within a city? The use of a city is not as a place to make things in, but as a place to carry on the transactions resulting from the transfer of the things made. The business transacted in a city is transacted with the offices and agents of the factory, not with the operatives. Therefore the factory space, the factory smoke and the operatives are all external matters introduced into city life only to clog its simplicity and ease of action.

Then look at the other side. The factory operatives come into town hastily in the morning only to go out of it in haste in the evening. Why should they do this, when their work could be done just as well in the suburbs? It is not work that is the labourer's curse, but want of leisure; and that he should be required to waste what little time he has that he could call his own

in going to and from home in crowded street cars—a journey that is likely to increase in distance continually, rather than to diminish,—is an evil which is not necessary; and to take steps to get over this state of affairs is to do the best thing that can be done to ameliorate the labourer's lot.

Whatever coming and going between factories and the offices and warehouses in town is necessary can be done more easily and perfectly by one or two persons, or, as it is done now, by an electric spark. It would not be necessary to do more than speak through the telephone, in most cases.

Does not this idea present a more alluring picture? Land is dear in the city, but out of it,—when once it is accepted that communication with the city is by telephone, motor or railway for individuals, there is nothing to hinder factories stretching freely over the land, with room for the hands to live about on land enough to have gardens which they can cultivate in the leisure saved by living near their work, and in this way add not only pleasure but profit to their lives.

It is inevitable that if the factories are placed where land is not too costly, the plan that Messrs. Lever Brothers have adopted, of making an industrial village, will be followed by other large works. There are other instances of the kind in England. There was an article in a recent Studio, giving an account of another institution of the kind, with a village in which the buildings were all designed by a good architect, making a very pretty village.

What the factories really want is not to be in the city but to be near the railway. They line the course of the railways, and that is why they come into town. What we want is both that the factories should be out of town, and that the railways should be with them. We are all agreed upon that point.

The thing to do is to bring in only such arms of the railways as are needed to deliver passengers and such goods for retail purposes as are necessary.

I have dwelt upon this point at some length, as I think that is really important. Present conditions are the cause of a great deal of backwards and forwards travelling in our own city and in most other cities, and to get over it in some way would not only lighten the labour but brighten the lives of the persons who work in the factories, and would make the city which is deprived of their presence a much more beautiful and agreeable place to live in.

That brings me to my next general point on City planning.

As the gate of a city has always been conspicuous, so at the present time the gate of a modern city, which is the railroad station, ought to be conspicuous. We have all known, no doubt, what an advantage this is in a strange city.

This brings me to inquire into the question which was brought before us by the World a few years ago as to the extension of Queen's Avenue, as they call it now, down to the Union Station. I have had a slide made to show what stands in the way of such a scheme being carried through. At the time the scheme was first mentioned there was nothing on the line but a few old buildings and a number of sheds. Now there are two solid buildings added. The difficulty this scheme met with was I fancy the idea that the work of making and paying for the new street would come upon us at once if the proposition were adopted.

There is a way of doing such things in France, which seems to the American Architect, from which I quote, to be "economical and judicious," "the practice," that is, "when a street needs to be widened, of condemning the land needed to carry out the alteration, and paying for the land alone, at a fair valuation. The buildings existing on the land are not disturbed, but the owners of the estates, in consideration of the purchase of the land, are prohibited from making any alteration in their buildings which will prolong the existence of the portion standing on the condemned land. In the rapid changes which go on in city life, it is seldom necessary to wait many years before the owner finds it for his interest to alter or reconstruct his building, and the land previously condemned is then thrown open to public use."

By a method of this kind it would be possible to plan for the future; so that a scheme for the well being of the city could not be obstructed by anything being done, which would make it impossible to carry out the idea when it becomes feasible to do it.

The next thing which I should like to consider in the planning of a city is the advantage of compactness. We recognize this advantage in the planning of a house. I think it will be found an advantage also that the city should be as compact as possible. I think we scatter along the ground too much in Toronto. That is a great disadvantage in many ways.

One of the trials of life here is the distances we have to go and the difficulty we have in getting about.

I remember when Toronto and Albany were about the same size, that is with about ninety thousand inhabitants. I lived in Albany for some time then, and was struck with the difference between what I could do in a given time in Albany and what I could do in the same time in Toronto.

Albany is built on the hillside, on the Hudson, and the whole town does not go back more than a mile, I should say, and does not extend two miles in length. Even at that time Toronto spread over a great deal of ground. The west end was then where it is, the east touched the Don, and Bloor Street did not bound the north very exactly.

Arriving at Albany by an early train, I went to the Capitol at half-past seven and made an appointment for nine o'clock. Then I looked up a lodging, and I remember going into two or three places before I was satisfied; after that I went down to the station and got my luggage, returned to my lodging, unpacked, made my morning toilet, and kept my appointment, all in an hour and a half; and I am not sure but I breakfasted, too.

What could one do in Toronto in an hour and a half in the way of going from the Union Station to the Parliament Buildings, then down to Church Street, to hunt up a lodging, thence to the Union Station, back to Church Street, shave, bathe, dress and get back to the Parliament Buildings; all by walking except for the necessity of a cab to bring up the luggage. This is an absolutely fair comparison of the relative position of localities and distances in two towns of an equal population, but built on a different plan.

I complain of the unnecessary distances, but there is more than that involved. Consider the nondescript character which it gives to the city.

We are proud of Jarvis Street, and a good street of that kind is an ornament to the city and agreeable to live in; but we do not want humble imitations of it all over the city.

These suburban streets and suburban residences in the heart of the city are misplaced. We cannot afford to give the space they really require. The houses are detached from one another but that is all. There is not room to put windows on every side. It is done; but the result is distressing even to look at in passing by. We should be much happier if we frankly adopted the idea of never having windows on the side, and put the houses close together.

I was going up Bond street, an old-fashioned residential street, the other day with this lecture in my mind, and was struck with the fact that it is really a more characteristic and interesting street than Jarvis street. I do not want to be misunderstood as saying that Bond street is a finer street than Jarvis street now, but it has the elements in it of the proper kind of beauty for a city street. There would be a row of three or four houses and then a big house with a little ground at the side of it. The contrast of solidity and openness gives a varied picturesqueness, beside which the straggle of houses all slightly detached but not essentially separated is monotonous and without character. Solidity is the first attribute of a city, and foliage or verdure interchanged with it, or backed by it, has twice the value it would otherwise have.

Another principle in all planning is that the best sites should be used for the best purposes. In a city the best sites should be used for public purposes. I think we have passed the time when private power or wealth can absorb the best there is in the city, and I think we may take it as a principle that the best site in the city should be taken up by the "city," as we say, that is for municipal purposes.

In Quebec the best site is Durham Terrace. The Citadel of course is also used for public purposes and may perhaps some day make an additional pleasure ground for the people.

At Montreal the same principle holds good. They have the Mountain park.

At Ottawa the Parliament buildings have the finest site in the city, or, in fact, I should think, in the province. Twenty miles from the city you can always see the Parliament buildings.

In Toronto we have a waterfront question. That is the principal thing we have at the present time.

The waterfront question is a railroad question and is really I think a relic of the past when the railroad and the shipping were of equal importance and worked together. I am afraid the only comfort we can take for the present, in this matter, is the understanding that the waterfront trouble has the live standing of a question. The waterfront has gone wrong, and the question is whether we can do anything to set it right. The more we think about the waterfront question, the more likely we are to find a solution for it. So let us hold to it that it is a question, a question for the future.

Everything that I have thought about in this lecture has brought more clearly to my mind the conviction that the movement the Guild of Civic Art is making, to have a plan of the city made for building to in the future, is a move in the right direction and is necessary.

The suburbs of continental cities, especially in Germany, in past years have been laid out by competition. The city makes terms with the owners of property according to the accepted plan. That is to say, the designers have a perfectly free hand about laying out the suburbs. I understand that results justify the method. The great point for us at present is not to lose chances for the future. Another point that we are all troubled over is the want of security or stability in investments in real estate and building. Nobody dare put up a decent house in any part of the city, because no one knows how soon the function of that part of the city will be moved away to another part. We cannot trust any neighborhood to remain of one character longer than twenty years. We do not know when a factory will encroach upon us, or when a tall apartment house will come alongside of our villa.

If a plan were fixed more definitely than now as to the way in which the city was to grow in the future, we would know more about what was to happen in the future and there would be more security in this direction.

Planning is a science, as I have endeavored to indicate, and it cannot be done hap-hazard.

That brings me to discuss the different kinds of city plan. There are three kinds of plan. There is first what is called the Gridiron plan; that is our own plan in Toronto, lines crossing one another at right angles. We have one or two curved streets, and I go by them whenever I can, for the purpose of seeing a curved street. The advantage of this plan is, of course, the simplicity in laying out, and it is said to possess the maximum building space. But our blocks are too large. Look at the great space between King street and Adelaide. They are now beginning to fill that up with factories. There is no reason why there should not through those places go what is very much needed in Toronto, diagonal streets. If we could not make a continuous one, we could I am sure make one that would be practically continuous. There are at present a series of discontinuous diagonal streets made by people who walk across the corners. A certain lot of people who live west come down to town via the lower part of Beverley street They live anywhere northwest but zigzag downwards for the sake of the corner cuts, and strike Beverley street near the bottom for the sake of the corners at the Grange, and the little square behind St. George's church. A gentleman told me that walking down from his house on Beverley street to his office east of Yonge Street, if he took advantage of all the turns, he could save five minutes in his walking. That shows the advantage of going along a diagonal street over going around a right angle. Two sides of a triangle are together greater than the third side.

There is secondly the plan on a ringed basis, as is shown in Vienna. (Here was shown a slide showing the plan of Vienna.) This ringed street is not a very large one. The old town is contained within the Ring Strasse which is a street of fine buildings presenting it is said a more dignified appearance than the streets which are straight. From that street all the other streets lead out. They say that every street car passes all the way around this ringed street and back to its own route, and that Vienna can be filled and emptied in a shorter time than any other city.

Milan, on a smaller scale, shows the same circular arrangement. There is the cathedral in the centre from around which they have pulled down the houses which once surrounded it and have made a fine large square into which all the street cars come.

Paris, you see, gets the same in a more extended form by the internal and external boulevards which surround the city. They are the line of the old fortifications which have been taken advantage of to make circular streets.

There is more than mere convenience in this arrangement. A curved street is a much more beautiful thing than is a straight street, and it is said to have the advantage that it is not so liable to jam. We are not troubled with jams here yet, but they are in the old towns, and to have a curved street is said to be a help to their avoidance.

The third plan is to have diagonal or radiating streets—streets diagonal to a square. It is usually a combination of the gridiron with the diagonal streets running across.

This slide shows the plan of Washington, which is the type of this design. Washington was laid off in advance. It is a specimen of a city which was laid out before it was built. It was laid off by L'Enfant who belonged to the school of landscape gardeners from which such things sprung in France. The city in the main runs with north and south and east and west streets, as are our streets here; but they have in all directions these fine diagonal thoroughfares, which are, of course, of great advantage for convenience in communication. It is also a great thing for air; they can get the winds from every direction brought into the city much more easily than where the streets are only in the two directions. It also gives in these little spaces formed by the intersection of the diagonal streets a motive for a great deal of variety in the building and decoration of the city.

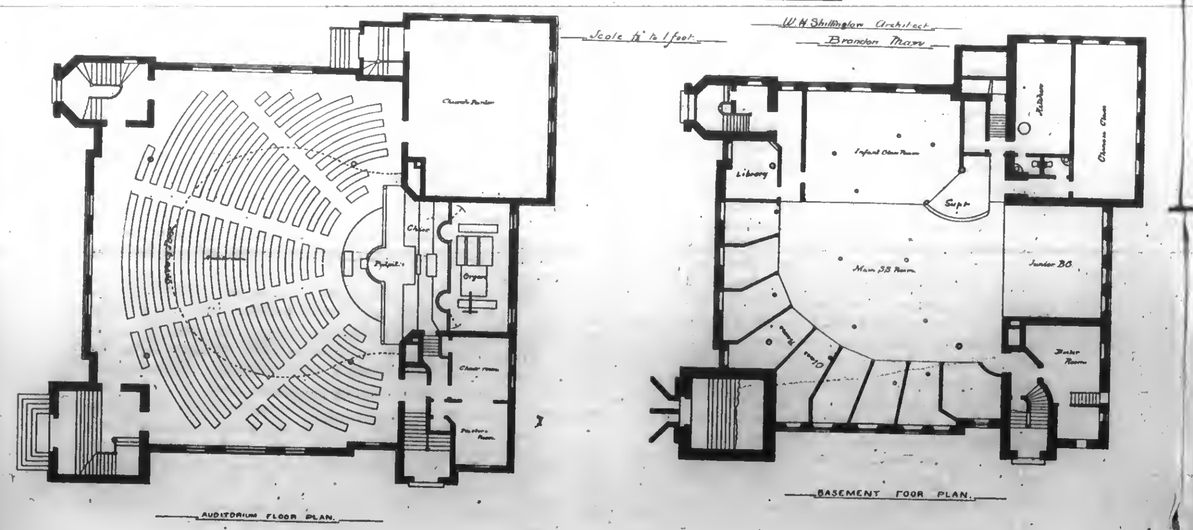
This is a sort of thing which might be superimposed upon Toronto for the benefit of our children. They are doing it in London; in Paris they have found it is not so expensive as one would think it is, because the number of additional frontages created by running a road through the middle of a block makes it partly pay for itself. We lose the frontage that is taken off where the street cuts through, but get instead two quite considerable frontages, so that there is actually more building space and more land to be sold than there was before.

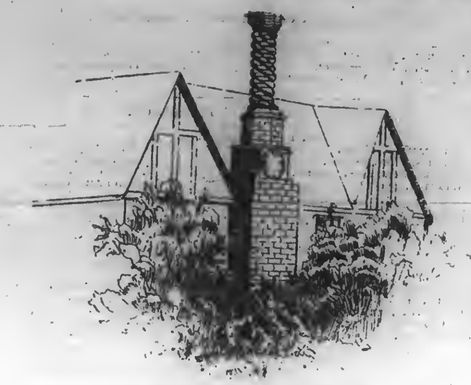
That concludes the general statement of planning, although one might go much further into it, but we have sixty slides to shew.

What I have tried to do is to show that in order to make a city beautiful, you have to attend in the first place to the plan. As far as convenience goes you see the nearer we can make our plan approach to that of a spider's web the better. What he wants is to get from the centre to any point in the shortest possible time. That is what we want, too.

We shall now go on with the slides, which each illustrate some point of plan, and they will be shown in blocks, according to the principle they illustrate.

ST. PAUL'S PRESBYTERIAN CHURCH, BRANDON, MAN.
W. H. Shillinglaw, Architect.





NORTHWEST LETTER.

WINNIPEG, April 5th, 1902.

The cold and the snow of winter have passed away and we are face to face with another building season. The indications are favorable for a prosperous year.

However, the old wage trouble is up again in connection with the carpenters and joiners This year the men have started early so that one of the objections to their action last year has passed away. Now their demands are known before the rush comes on. It is a vexed question, hard to solve in a manner satisfactory to all parties concerned. It admits of many arguments pro and con—points that have been debated and re-debated so many times that they are almost worn threadbare by by this time. The minimum wage of 32 cents per hour is in evidence but in our mind this is not considered by the men the most important point ; the recognition by the contractors of their union seems still to be the strong undercurrent which may carry both sides on to the rocks of disagreement and trouble. While we are willing to acknowledge that the unions are altogether within their rights in banding themselves together for their own protection and the advancement of their trade, we doubt the advisability of trying to force on the contractors the question of the union's recognition. We believe in a good wage for good men, and if in some way the poorer class of men now in the trade could be weeded out and classified as carpenters helpers and paid a fair wage for the work performed, till they could work as good carpenters able to earn for those who employ them a fair equivalent for the wage paid it would in some measure we feel right the matter. It must appear to all that in the long run it pays to employ good workmen and it also pays to pay a good wage to good men—men who will do a fair day's work for a fair day's pay. We look and wish for a closer bond of fellowship and a truer commingling of interests between capital and labor, for their interests are one and the same if looked upon in the right spirit is a spirit of fairness, a spirit of honesty in word and action, a spirit of friendliness and a desire that the interests, monetary and otherwise, should be respected. This may be a high ideal but one which if attained to would end most, if not all the labor disputes of the present day.

The buildings at present proposed are mostly of the better class. This is good evidence of the general prosperity of the community and from an architectural standpoint is most desirable, as architects in this country are so bound down to the lowest cost that there is very little opportunity to work in good good detail and ornament.

There is room in this city for a good modern house at a medium rent. As a rule rents are high, and what the average man requires is a comfortable house not too far from the centre of the city and at a rent which could be paid out of a moderate salary. To the capitalist who will put up such houses and solve the high rent problem there is certainty of a good return on the investment. The house must be warmly built, but while this is called a cold country we maintain that the amount of fuel if judiciously used should not exceed the amount used in Ontario, because as a rule we build much warmer.

A measure of great importance to the architectural profession in this city and province has for a time at least been shelved by the Legislature. The civil engineers and architects of the city and province proposed to form an Engineering and Architectural Institute and for this purpose had applied to the local Legislature for a charter of incorporation. The bill met with much opposition from various quarters. The Dominion land surveyors gave strong opposition. They being a close society objected to the civil engineers having certain powers as to surveys and plans which they said were exclusively their own, or in other words they had obtained a good thing from the Legislature many years ago and were determined to hold it if possible. Vested rights w a the cry, and in some measure this cry prevailed.

The section referring to the architects met with perhaps greater opposition, and from quarters least expected. The architects have proposed to regulate the entrance into the Province o foreign plans and to confine the preparation of plans and designs to all practicing as architects in the city or province at the present time, or who might register as architects within six months after the passing of the Bill. A provision was also made for an entrance examination for all wishing to enter and practice after the six months.

The intention of the Bill was to try and raise the standard of the profession, and throw around it such safeguards as would be beneficial to the general public, as well as the architects. To do this requires a certain amount of protection which can only be obtained through legislation. It was thought the Bill would lay the foundation on which architecture might be gradually raised to a position of prominence in our Province, but the benefits would accrue not so much at the present time as in the years to come. Such were the ideas of those who backed up the measure.

The labor party blindly opposed it on the so called ground of monopoly—a strange and inconsistent stand for the party to take, as their very existence is based on a general monopoly with a tyrannical clause incorporated therein. It seems strange that they cannot see that to raise the standard of architecture, would mean at the same time advancing their own trade interests. In no way would it interfere with them.

Another party strong in opposition (and least expected) was the local Builders' Exchange. Their opposition seems to have been taken from a selfish stand-point. It would appear that they wish to draw plans or have them drawn, then put in tenders for work and execute it without inspection, and so monopolize the whole, a good thing for them perhaps, but not to the best interest of the owner or the general public. They stated that the Building By-law (so-called) safe-guarded the public interests without the assistance of qualified inspection, &c., but like most By-laws of this nature drawn up by those not fitted for the work, one can make anything out of it, and its provisions may be carried out or not as influence may direct.

The above was part of the opposition which the Bill received, and while it passed through the committee stage with some amendments, it was thrown out in the House. We trust in the near future it may appear again, and may then receive fair treatment at the hands of the members. In the meantime it has started the ball rolling, and aroused we trust among the architects of the Province, a general desire to see the profession placed on a good basis and receive at the same time a fair amount of legislative protection.

ST. PAUL'S PRESBYTERIAN CHURCH, BRANDON, ONT.

This church, illustrations and plans of which are given on preceding page, was designed and erected last year under the direction of Mr. W. H. Shillinglaw, architect, of Brandon, Man. The basement is constructed of local field stone and the superstructure of white brick with Bedford limestone trimmings. The auditorium, including gallery, has a seating capacity of 1,000, and the Sunday school in the basement of 500. The building is heated by steam on the direct indirect system. The total cost was $40,000.

NOTICE TO SUBSCRIBERS.

Subscribers who may change their addresses this spring are requested to advise us of the fact, and send us promptly their new addresses, thus insuring correct delivery of their papers.

At the last weekly meeting of the Toronto Chapter of Architects, Mr. E. Burke was re-elected president, and Mr. Moore, secretary.

Equal parts of pure red lead and powdered glass with equa parts of albuminized and boiled linseed oil as a medium, is considered to be one of the best anti-corrosive paints.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD)

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited,
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.
Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address Notify the publishers of any irregularity in delivery.

N. T. GAGNON, Secretary.	LOUIS PAYETTE.

NOTES.

John and James Campbell, of Seattle, have purchased the well-known McKean stone quarry, at Picton, and will put in machinery to properly develop the property.

As a result of a recent conference between the architects and master builders of Toronto, the architects have agreed to specify that the carpenter contractor shall put down the permanent floors in buildings under construction called for by the amended building by-laws.

The Prussian Minister of Public Works offers prizes of 5000 3000 and 2000 marks for the best apparatus for measuring wind pressure, and a further prize of 3000 marks for the instrument which has the best record after a long trial. The competition closed on April 1st.

The Royal Canadian Academy at its recent meeting in Montreal elected the following officers:—President, Robert Harris, Montreal; Vice-President, A. C. Hutchison, Montreal; Secretary-Treasurer, James Smith, Toronto. Mr. Wm. Hope, of Montreal, was elected an R. C. A., and J. G. Franchere, of Montreal, and W. St. Thomas Smith, of Toronto, R. C. A's.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

PERSONAL.

Mr. G. A. Reid, R. C. A., has resigned the Presidency of the Ontario Society of Artists, after many years of faithful and efficient service.

Mr. Peter McMichael, of the James Robertson Co., St. John, N. B., is said to have received the appointment of general manager of the Dominion Radiator Co., of Toronto, in succesion to Mr. John M. Taylor.

Mr. G. S. Lemasine, the young English designer, who has spent some months in the office of Messrs Darling and Pearson, and Ald. S. G. Curry, architects, Toronto, is about to take a position with Messrs Castle & Son, of Montreal. Mr. Lemasine is the author of the paper on the Field of Design, and the clever sketches illustrating the same presented recently before the Ontario Association of Architects, and printed in the CANADIAN ARCHITECT AND BUILDER for March.

Mr. Gordon, of the firm of Gordon and Helliwell, architects, who left Toronto a year ago to execute a commission in Corea, for the American Presbyterian Church, is now in Pekin, where he will erect a hospital building. Brick is the material principally employed, but it is not up to the Canadian standard, and the same can be said of the native workmen. Mr. Gordon's Toronto friends will be pleased to hear that he is enjoying good health, and gaining experience of a novel and interesting character.

Messrs. Darling and Pearson, architects, Toronto, have decided to open a branch in Winnipeg. Mr. Percy Over, who has been with the firm for a considerable time, left Toronto for Winnipeg on Saturday last to take charge of the office in that city. Mr. Over will be greatly missed, especially by the younger members of the profession in Toronto, on account of the active part which he has taken in connection with the students' classes which have met weekly in the O. A. A. rooms during the past winter.

Mr. James Bloomfield, of Messrs Henry Bloomfield & Sons, artists in stained glass, Vancouver, B. C., spent a few days in Toronto, last month, while en route to New York. While there, he made the acquaintance of the leading workers in glass, and artists in other lines, and carried away a favorable impression of the city. He is looking forward to the time when Vancouver shall have so grown in population and wealth that her citizens will have more leisure than at present to devote to matters artistic.

An informal luncheon was tendered Mr. G. S. Lesmansie and Mr. Percy Over, in the O. A. A. rooms, Toronto, on the eve of their departure for Montreal and Winnipeg respectively. Mr. W. A. Langton fittingly expressed appreciation of the services rendered by these gentlemen in behalf of the educational work of the Association, the regret occasioned by their departure, and the hope that at some future time they might find their way back to Toronto. Mr. Lesmansie was presented with a pipe and case, and Mr. Over with a full set of Shakespeares' works as mementos of the occasion, and a slight expression of hearty good will.

John and James Campbell, of Seattle, have purchased the well-known McKean stone quarry, at Picton, and will put in machinery to properly develop the property.

As a result of a recent conference between the architects and master builders of Toronto, the architects have agreed to specify that the carpenter contractor shall put down the permanent floors in buildings under construction called for by the amended building by-laws.

The Prussian Minister of Public Works offers prizes of 5000 3000 and 2000 marks for the best apparatus for measuring wind pressure, and a further prize of 3000 marks for the instrument which has the best record after a long trial. The competition closed on April 1st.

The Royal Canadian Academy at its recent meeting in Montreal elected the following officers:—President, Robert Harris, Montreal; Vice-President, A. C. Hutchison, Montreal; Secretary-Treasurer, James Smith, Toronto. Mr. Wm. Hope, of Montreal, was elected an R. C. A., and J. G. Franchere, of Montreal, and W. St. Thomas Smith, of Toronto, R. C. A's.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

PERSONAL.

Mr. G. A. Reid, R. C. A., has resigned the Presidency of the Ontario Society of Artists, after many years of faithful and efficient service.

Mr. Peter McMichael, of the James Robertson Co., St. John, N. B., is said to have received the appointment of general manager of the Dominion Radiator Co., of Toronto, in succession to Mr. John M. Taylor.

Mr. G. S. Lemasioe, the young English designer, who has spent some months in the office of Messrs Darling and Pearson, and Ald. S. G. Curry, architects, Toronto, is about to take a position with Messrs Castle & Son, of Montreal. Mr. Lemasine is the author of the paper on the Field of Design, and the clever sketches illustrating the same presented recently before the Ontario Association of Architects, and printed in the CANADIAN ARCHITECT AND BUILDER for March.

Mr. Gordon, of the firm of Gordon and Helliwell, architects, who left Toronto a year ago to execute a commission in Corea, for the American Presbyterian Church, is now in Pekin, where he will erect a hospital building. Brick is the material principally employed, but it is not up to the Canadian standard, and the same can be said of the native workmen. Mr. Gordon's Toronto friends will be pleased to hear that he is enjoying good health, and gaining experience of a novel and interesting character.

Messrs. Darling and Pearson, architects, Toronto, have decided to open a branch in Winnipeg. Mr. Percy Over, who has been with the firm for a considerable time, left Toronto for Winnipeg on Saturday last to take charge of the office in that city. Mr. Over will be greatly missed, especially by the younger members of the profession in Toronto, on account of the active part which he has taken in connection with the students' classes which have met weekly in the O. A. A. rooms during the past winter.

Mr. James Bloomfield, of Messrs Henry Bloomfield & Sons, artists in stained glass, Vancouver, B. C., spent a few days in Toronto, last month, while en route to New York. While there, he made the acquaintance of the leading workers in glass, and artists in other lines, and carried away a favorable impression of the city. He is looking forward to the time when Vancouver shall have so grown in population and wealth that her citizens will have more leisure than at present to devote to matters artistic.

An informal luncheon was tendered Mr. G. S. Lesmansie and Mr. Percy Over, in the O. A. A. rooms, Toronto, on the eve of their departure for Montreal and Winnipeg respectively. Mr. W. A. Langton fittingly expressed appreciation of the services rendered by these gentlemen in behalf of the educational work of the Association, the regret occasioned by their departure, and the hope that at some future time they might find their way back to Toronto. Mr. Lesmansie was presented with a pipe and case, and Mr. Over with a full set of Shakespeares' works as mementos of the occasion, and a slight expression of hearty good will.

Now Ready—Third Edition

CANADIAN CONTRACTOR'S HAND-BOOK AND ESTIMATOR.

The third edition of the Canadian Contractor's Hand-Book has been published and is now on sale. The book has been revised and enlarged to upwords of two hundred pages, and the title changed to the Canadian Contractor's Hand-Book and Estimator, considerable matter bearing upon the cost of performing various kinds of work having been added.

The price of the third edition, mailed free, is $1.00 to subscribers of the CANADIAN ARCHITECT AND BUILDER, and $1.50 to non-subscribers. Order from the publishers,

LESSONS OF THE PARK AVENUE HOTEL FIRE.

The recent fire in the Park Avenue Hotel, New York, caused but little damage to the building, which proved to be a good example of fireproof construction. The floors were of iron and brick, the partitions of brick and the elevators and stairways enclosed in brick walls. The fire was confined to the main hall. A sad feature of the occurrence, however, is the fact that several persons were snffocated by the smoke which entered their rooms from the halls and stairways through the crevices around the transoms and doorways. This is a new phase of the fireproofing problem to which attention must be given in the future.

MOUNT ROYAL CREMATORIUM.

The Mount Royal Crematorium, Montreal, built from the designs and under the superintendence of Andrew T. Taylor, F. R. I. B. A., architect, Montreal, is now completed. So far as known this is the first building of the kind to be erected in Canada. The crematorium is situated to the left of the entrance of Mount Royal Cemetery.

The gateway and the porch lead to a large conservatory hall, about 81 x 42 feet inside. The conservatory will serve a double purpose. It will be used as a waiting hall for the crematorium, and also for the winter vaults, which are located beyond. From this conservatory a door leads into an ante-room, from which another leads into the crematorium proper. This latter consists of two portions, a waiting hall and a chamber in which the incinerators are placed. The conservatory has a high glass roof, with ornamental iron trusses, and a floor of mosaic marble, and will be kept well filled with flowers. The crematorium proper is lined with marble. It has an arched roof and and windows, fitted with leaded lights. A portion of of it is lined with white tiles. The idea is to make the whole pleasing and attractive without extravagance or over ornamentation.

The style of the building is Gothic. Montreal limestone is used for the walls. The doors are of oak. The conservatory has large plate glass windows. The building will be heated by hot water pipes. The incinerators are of the most modern arrangement. Room for four incinerators have been allowed, but two only are built at present.

NOTES.

Mr. Henry Martin, A. R. C. A., who has of late given special attention to the painting of architectural subjects, has on view at Matthews' Gallery in Toronto, an interesting collection of water colors of his character.

A by-law of the London County Council enacts that no house, building or other erection shall be erected upon any site or portion of any site which shall have been filled up with dust or other refuse, or in or upon which any such matter shall have been deposited unless and until such refuse shall have been properly removed by excavation or otherwise from such site.

The following are the names of the successful candidates in Architectural Drawing and Building Construction at the recent closing examinations of The Toronto Technical School. Class 1.—I. Ritchie, W. H. Martin, A. Boissoneau, W. Young, G. Skinner, R. J. Webb, F. Markham, H. J. Baker, S. Young, A. Harriman. Class 2.—A. Fisher, A. R. Boyle, F. W. Robinson, H. Anthony. Pass—F. Essex, W. J. Randall, A. P. Allan, Leslie Price.

The Inland Architect has commenced the publication of a series of notes by architects in general practice in the United States, showing the cost per cubic foot of different kinds of buildings. Messrs Janney and Mundie report the cost of a number of fire proof buildings in which iron and steel construction was employed. The figures cover a wide range from 7 4-10 cents per cubic foot for a warehouse and manufacturing building, and 10 1-5 cents for stables, to 17 1-5 cents for an apartment building, and 20 cents to 57¼ cents for office buildings.

Fire Resisting Construction.

The Royal Insurance Company, of Liverpool, has had printed and circulated a form of specification for rendering buildings less liable to destruction by fire. It provides that buildings shall not exceed 80 feet in height. Above the ground floor glass is to be ¼ inch thick in sections not larger that 2 square feet. In the case of wired glass sections are to be not less than 4 square feet. For external wal's, brick terra cotta and concrete are to be used. Stone may be employed as facing when backed by not less than 13 inches of brick. On buildings constructed in accordance with this specification, the Company will make a reduction in their rates.

Spruce Lath.

THERE is said to exist a slight prejudice against the use of spruce lath on the ground that sometimes they discolor the plaster. Recent inquiries from leading contractors in the Maritime Provinces would seem to disprove this contention. Messrs. B. Mooney & Sons, of St. John, write that they have never seen any stain or discoloration from spruce laths, and that, when clear of sap and wane, they give good satisfaction. In the eastern markets, including Boston, New York, and Philadelphia, spruce laths made from slab stock bring higher prices than any other. It is claimed that pine laths containing knots or balsam will discolor the plaster, whereas this drawback is not met with in the case of spruce. As the merits of spruce laths become more generally known a greater demand for them will develop.

The Decay of Stone

Alarm has been caused the citizens of Glasgow by the discovery that the stone work and especlally the costly carving on the minicipal huildings is showing marks of rapid decay. The buildings were erected but a few years ago at a cost of about $2,500,000, stone from a newly opened Bannockburn quarry being used. As a test of the stone it was allowed to lie for a year in the builder's yard before being placed in the building. Although it stood this test satisfactorily, it began to decay in situ. The reason has not been discovered. Much older buildings in the same locallty are in a good state of preservation. Instead of cutting out whole capitals of pilasters, as was at one time proposed, only the decayed portions are being cut away and a silicate solution applied for purposes of preservation. £600 has already been expended on this work.

Dangers of Steel Construction.

General Sooysmith, head of one of the most prominent contracting firms in the United States, in a recent address before the Chicago Real Estate Association predicted

the early collapse of many of the tall buildings of that city in which imperfect steel construction has been employed. In the earlier buildings of this class, the steel framework instead of being imbedded in concrete, was simply cased with stone or brickwork, leaving crevices through which moisture might enter and corrode the metal. Under such conditions corrosion proceeds very rapidly, and the corrosion of one fifth of the substance of the metal of a supporting member at any given point, would in general, cause its failure. In view of General Snoysmith's warning it is urged that an immediate examination should be quietly made of buildings of the class to which he has referred, and measures taken to prevent an accident which would involve loss of life and so weaken public confidence in the stability of such structures as to seriously depreciate their value. Such an examination would also be likely to disclose facts of which architects should be possessed.

Reform in Architectural Competitions

By request of a number of prominent British architects, the Royal Institute will appoint a special committee to receive suggestions and formulate a plan whereby necessary reforms may be effected in the method of conducting competitions. In view of the unsatisfactory results of several important competitions held recently in England, the conclusion has been reached that in undertakings of a technical or complicated nature more than one referee is required. It is suggested that in such cases there should be two—one to be chosen because of undoubted ability as a designer the other for his special knowledge of the particular problem to be considered. In case these two should be unable to agree to an award it is proposed that they be empowered to elect a third architect as umpire. It is suggested that a list of architects in whom competitors have confidence be supplied to the president of the Institute, from which list a choice of referees could be made. It is urged that in cases where the promoter of a competition fails from any cause to carry out the undertaking it should be agreed that a substantial money payment should be made to the author of the selected design on about the same scale as if he has been commissioned direct to prepare plans without any competition.

Labor Conditions.

THE opening of the building season this year has been marked by more than the usual number of strikes embracing bricklayers, carpenters, painters, plumbers, and last of all the architectural structural ironworkers. Most of the disputes have been adjusted for the present season at least on a compromise basis, without much loss of time. The higher standard of wages which has been fixed in the various trades, has blocked quite a large percentage of building projects which would otherwise have gone forward this season. As an example a contractor who submitted tenders for four buildings states that only one of the four was proceeded with on account of the tenders being too high. The opinion prevails that the ever increasing demands of the unions for higher pay and shorter working hours, coupled with other restrictions almost too numerous to mention, will prove to be one of the most potent influences in bringing to an end the present period of prosperity. The broadening of the franchise has placed great political power in the hands of the labor leaders, which they have not been slow to exercise. As a result legislative bodies are pandering to them as never before, and are in danger of losing sight of the national welfare, which demands equal justice to all classes and the protection of capital as well as labor. It should not be forgotten that the interests of both are indentical and that any advantage given the one over the other can only be temporary. We should take warning by the experience of our sister colonies of Australia where the results of the labor laws are thus described in a letter by Mr. D. H. Ross, a Canadian, to Sir Richard Cartwright, Dominion Minister of Trade and Commerce: "The labor laws throughout the Commonwealth and New Zealand are of such character that the careful business man or capitalist seeking an investment would hesitate indefinitely before placing his business and capital under the sole control of the labor unions, which are so strong at the present time that they practically hold the balance of political power, and throw in their support with either party, Government or Opposition, which will agree to carry out their so-called labor reforms. A manufacturer's business is under their control to the extent that they dictate its policy, the number of employees permitted, the number of apprentices, their hours of labor, their rate of wages, their days of vacation, how the factory shall be lighted and ventilated, and so on, ad lib. Owing to these tyrannical labor laws, boot manufactures in Melbourne, who, previous to the federal tariff were protected to the extent of $1.20 per pair on men's boots, were scarcely able to make both ends meet. In Wellington, N.Z., it was recently stated that a large boot manufacturer there had decided to close his factory and become an importer, and boot operatives have recently arrived here from New Zealand looking for employment."

The Coronation Stone.

THE near approach of the coronation of King Edward the VII lends interest to the following particulars regarding the history of the famous coronation stone: That this stone was formerly in use in Ireland for the Coronation ceremony, that it found its way into Scotland—certainly earlier than the reign of King Kenneth, 834—that it was then removed to the Abbey of Scone, where for 450 years all the kings of Scotland were crowned upon it, and that it was brought to England by King Edward I. in 1296 after John Baliol, the Scottish King, had been defeated at Dunbar, are well ascertained historic events. There used to be a tradition that the stone was of meteoric origin, but Dean Stanley settled this matter when in his "Memorials of Westminster Abbey" he included a paper written by Professor Ramsay, called "A Geological Account of the Coronation Stone," in which it is said: "The stone is a dull reddish or purplish sandstone, strongly resembling that of the doorway of Dunstaffnage Castle, which was probably built of the stone of the neighbourhood. It is extremely improbable that it was derived from the rocks of the hill of Tara, from whence it is said to have been transported to Scotland, neither could it have been taken from the rocks of Iona. That it belonged originally to the rocks round Bethel is equally unlikely, while Egypt is not known to furnish any strata similar to the red sandstone of the Coronation Stone."

PORTION OF CHIMNEY HOOD FOR DRAWING ROOM IN RESIDENCE OF MR. F. B. FETHERSTONHAUGH, DESIGNED AND EXECUTED BY THE ELLIOTT & SON CO., TORONTO.

A STUDY OF THE BASIS OF PROFESSIONAL ETIQUETTE.

Not long ago a speaker, at one of the English architectural meetings, spoke in a congratulatory way of the time being past when a leader of the profession (the allusion was evidently to Sir Gilbert Scott) would go about with a portfolio of churches under his arm, to call on building committees. On the other hand, we hear that in the United States, nobody dare wait for a job to come to him; that Michael Angelo himself, if he lived in Chicago or New York, would have to hustle for work. Which of these two tendencies is in the direction of progress?

What is all this hustling about? What is there about hustling that should recommend it to clients? The hustler is not hustling for his client's interest but for his own. A scholarly designer like Sir Gilbert Scott must have been a very high-class hustler. His kind of work implied personal attention to it. Yet there is a story of his going to a church opening, and, as he was being driven up to the church, turning pale and whispering to his confidential clerk, who was with him, "They have got the wrong church."

The typical hustler works *for* work not *at* it, and what the client wants is some one who will work *at* his work.

Of course the hustler works at his client's work in the sense of getting it through. He must have a good staff. That is partly what he is hustling about. It almost seems sometimes as if there is a point of view from which it is the staff which may be said to have a hustler, who spends his time upon the street to find work enough to pay them. Staff work, in fact, is the result of this system.

There is a certain medium class of commercial work for which staff work does well enough, and a certain class of client to whom it is a satisfaction to feel that his work is being handled in what he would call a business like manner; i. e. put through without fuss, in the shortest possible time, and looking when done like other new buildings of its kind. As a matter of fact the work is done in a business like manner. Let us give the style of practice all the credit that is due to it, in the best examples. The architect runs a plan factory. It has factory merits and factory defects. The merits are certainly a comfort to a client whose interest in his building is commercial; and the defects do not matter much from his point of view. But how about delivering over the whole field of architecture to this system? It is bound to result in staff architecture, that is to say in factory architecture; and factory architecture is not good enough for good work. Any body who knows what real planning is like will know that the case of Sir Gilbert Scott will be often repeated in a metaphorical sense. The right problem may be under consideration but the wrong plan will be produced. It is true that H. H. Richardson did not draw himself, but his mind was on design all the time; he was devoted entirely to his work. It is true on the other hand that Mr. Ernest George (as he stated when receiving his R.I.B.A. gold medal) does nothing else but draw. He represents, that is to say, the possibility of a first-class man taking care of the design, while some one else gets the work and attends to the business connected with it. But Mr. George is as exceptional in his way as Richardson was. Under ordinary circumstances, if work has to be worked for, the big man of the concern will be devoted to that, as indeed he is now, and the architectural level must fall. That is bad for architecture, but what we are concerned with just now is that it is bad for the owner of architecture—the client. If this estimate of the consequences of hustling is sound, clients have no cause to smile upon the practice.

How about the architects themselves? The profession professedly abhors the practice; and, at the end of the tariffs of fees, there is a clause defining professional etiquette in a way that practically excludes work hunting. But there commonly is a jocular way of speaking about the practice that implies uncertainty of purpose. At the bottom of this is uncertainty about the moral basis, a feeling that perhaps the new is the true and that old fashioned scruples are perhaps old fashioned for cause, like horsecars and the old, old systems of fifteen years ago. Morals however do not change. A gentleman is the same now as he was in

the days of "the grand old gardener and his wife", and as he will be when he walks the golden street of the new Jerusalem. It is this permanent quality of honour that attracts the regard of the architectural profession. The superficial points in professional etiquette may change; ideas of professional dignity may change; ideas of remuneration may change; the basis of these is not too deep for ioking; but the matter of getting work is.

The truth seems to be that there is only one way of getting work that is right, and that is that an architect should always do his best work: put his best goods upon the market, that is to say, and let them speak for him.

It is a hard condition, for growth from small to large work may be slow. People who employ an architect for important work, like to see something that he has done of the same kind. "We judge ourselves by what we think we can do, but others judge us by what we have done," is a maxim which exactly fits the case of the young architect and states his difficulty. Competition (a question by itself) is accepted as a means of making a rapid step between small work and large. But, competitions or not, the step is sure to come in time to the really able, and usually before long; so that, though, like all other right conduct, some patience and faith and self-government are implied, the condition, though severe, is not more than a man should accept.

Why is this the condition of honourable practice? Because the moment a man reaches out for work he is reaching out for somebody else's work. If the work would not naturally come to him, it would naturally go to someone else. He reaches out for it; uses a "pull," asks, persuades, or merely works the magnetism of his personal presence—highly magnetized for the occasion—and the deed is done; he has knifed a neighbour.

This is the bottom fact that makes the profession uneasy about going about to get work. It is the disregard of others that is the dividing line between honourable and dishonourable practice. When another architect is already engaged, it is easy to recognize that he has rights and the better members of the profession are strict about not interfering there. It is a more uncertain state of affairs when work is in the air, and seems to be only waiting to be grasped. It is agony not to grasp it, but there is always a sense of shame before other members of the profession in doing so—and is not this the cause, that it has to be taken from some other member of the profession. If it is our's we may wait for it; if it is not our's whose is it? Somebody else's. Then for "taken from some other member of the profession", we may read, "stolen from some other member of the profession". It seems strange that men should think their duty to their wife and family obliges them to steal from some other man's wife and family. And this in a Christian land. Surely before we adopt the (reputed) American practice we should pause to think where we are going.

W. A. LANGTON.

The most magnificent work of architecture is the Taj Mahal, in Agra, Hindustan. It is octagonal in form, of pure white marble, inlaid with every sort of precious stone. The work took 22,000 men 20 years to complete, and though there were numerous gifts and the labour was free, the cost was £3,200,000.

BY THE WAY.

In view of the injury sustained by several persons by the recent fall of a balcony in London, the Builder suggests that District Surveyors should be instructed to examine balconies on streets through which processions will pass during the coronation ceremonies.

× × ×

I am interested to learn by what standard candidates for membership in the Ontario Society of artists are judged? A certain amateur artist was asked by the society to allow some of his works to be hung at the recent exhibition. His pictures attracted favorable notice and several of them were sold, yet I am told the artist was refused admission to membership in the society.

× × ×

The death of a man who recently fell over the stair railing in the City Hall, Toronto, has called attention to the proper height for such railings. The coroner's jury appointed to enquire into the cause of the accident returned a verdict of accidental death, but expressed the opinion that the railing was too low, and to insure safety should be made higher. On the contrary the architect of the building, Mr. E. J. Lennox, states that the railing corresponds to what has always been regarded as the standard height, namely 2 feet 6 inches. The matter is one which architects would do well to enquire into, lest some day they find themselves in the position of defendant in an action for damages.

× × ×

A young architect came to me the other day with a grievance which I am sure is shared by many citizens of Toronto. He had been out with his camera with the purpose of getting pictures of some of the best examples of domestic architecture in Rosedale, the annex, and other residential districts. In almost every instance he found a telephone or electric light pole, a real estate agent's sign or some such disfigurement so placed as to make it impossible to secure a satisfactory photograph. There is little encouragement given the citizens to build tastefully so long as unsightly poles and signs can be planted in front of their doors. It is time that the telephone company should follow the example of the electric light company which of late, in the best residential localities, has been steadily putting its wires underground.

× × ×

The property owners on Spadina Crescent, in one of the principal residential districts of Toronto, recently made the discovery that a livery stable was to be established in their midst. When they had set about getting up a petition to the Council, they learned that the limit of time allowed for filing a protest had expired. They are consequently without redress. This is but another instance of the hardship to which property owners are subjected because of the defective character of the city building by-laws. Owners of property should not be required to be constantly on the watch against encroachments upon their rights. The by-laws of the city should afford them protection. Under the existing by-laws, factories and other objectionable buildings can be erected anywhere, regardless of their effect on the beauty of the locality and the value of surrounding property.

ARCHITECTURAL LEAGUE OF AMERICA.

The fourth annual convention of the Architectural League of America will be held in Toronto on the 29th, 30th and 31st inst. About fifty delegates are expected. The League was originally organized to facilitate club work and exhibitions, but has since broadened its field. The principal topics of discussion this year will be Architectural Education and Municipal Improvement.

The Toronto Architectural Eighteen Club, being hosts of the occasion, are holding their annual Exhibition open until after the convention and also arranging to show the delegates and their friends around the city and give an entertainment on the last evening of the convention.

The draft programme for the convention, which of course is in some degree subject subject to change, is as follows:

THURSDAY, MAY 29th.

9 a.m.—Meeting of the Executive Board at the Queen's Hotel,
9 a.m.—Registration of delegates, alternates and visitors at the Ontario Society of Artists' Galleries.
10 a.m.—Calling to order of first meeting by President of Toronto Architectural Eighteen Club.
A.—Roll call of representatives.
B.—Appointment of Committee three on Records and Publicity.
C.—Election of Speaker and Secretary of Convention.
D.—Election of two auditors to examine and report upon the Treasurer's accounts.
E.—Reading of Communications.
F.—Annual Report of Executive Board.
G.—Treasurer's Report.
H.—(1) Report of Committee on Publicity and Promotion, Lawrence V. Boyd of Philadelphia, Chairman.
(2) Report of Committee on Code of Ethics and Competitions, Julius F. Harder of New York, Chairman.
(3) Report of Committee on Exhibition Circuit, Walter F. Kleinpell of Chicago, Chairman.
(4) Report of Committee on Foreign Exhibit-Committee not filled.
(5) Report of Committee on Current Club Work, Ernest J. Russell of St. Louis, Chairman.
(6) Report of Committee on Education, Julius F. Harder, of New York, Chairman.

AFTERNOON SESSION.—2 P. M.—Discussion on Educational Questions under the following eight headings set out by the Educational Committee and allotted to the various Clubs:

1.—INTRODUCTORY.—Three functions of the science of education;
(a) The information of knowledge.
(b) The discipline of human faculties.
(c) The nurture of character and individuality.
2.—(d) Is a National American Art University a desirable or necessary institution?
(e) Should the art education of the nation be centralized in one great school, and therefore the present schools be united with such central school, and detach from their present associations with other fields of instructions?
3.—(f) Should the National Government have connection with and jurisdiction over a National art university, or should the organization and control be similar to that now existing in American universities?
(g) Would the artistic growth of the nation reach its highest development without a great National centralized university?
(h) Could the present centers of art education scattered in reference to locality and influence, and developing more or less independently attain to as high a total of efficiency and accomplishment?
4.—(i) Is the time ripe for a great American University of Art?
5.—(j) What should be included in its curriculum?
(k) Should art artisanship, namely, the art-crafts be included?
(l) Should a national university be one primarily for the arts and crafts, and secondarily for the fine arts?
(m) Are the concrete or applied arts superior to the abstract or luxurious arts?
(n) Are the concrete or applied arts entitled to more immediate consideration than the abstract or luxurious arts?
6.—(o) Does architecture belong in the category of the accepted fine arts, or is it more properly related to art craftmanship?
7.—(p) Does the one great centralized national university, or do the many smaller provincial schools exert the stronger and better influence over the studeot body?
(q) Which of the two systems gives the greatest freedom and promise for the development of individuality?
8.—(r) Can a system of self-education by means of club association be permaneotly established?
(s) Is such a system demanded by present conditions?
(t) Would such a system, seriously undertaken, self-supporting, and maintaining itself by methods of self-government, be productive of commensurate results both of quantity and quality?
(u) What should be the plan and scope of such a system of club and inter-club sell education.
(v) Can a connection be established between such a system and the architectural educational institutions?
(w) What should and could be the nature of such a connection?

EVENING SESSION—8.30 p.m.—Municipal Improvement Committee's Report.
Lantern Slides of improvements to City of Washington with lecture on same by Mr. H. K. Bush-Brown of New York, Chairman of this Committee.

FRIDAY, MAY 30TH.

9.30 a.m.—Address on Landscape Architecture by Geo. F. Pentecost, Jr., of New York.
Paper by Frederic Law Olmsted, of Brookline, Mass.
Paper on "Civic Aesthetics" by Charles Mulford Robinson, of Rochester, N. Y.
2.30 p.m.—Sail on Lake Ontario. Group photograph in front of Toronto University.
EVENING SESSION—8.30 p.m.—Lecture on Mural Decoration by H. B. Pennell, of Boston.
Lecture on Municipal Improvement at the St. Louis Exhibition, by Albert Kelsey.

SATURDAY, MAY 31ST.

9.30 a.m.—Address on "Architectural Practice in America", by Dwight Heald Perkins, of Chicago.
AFTERNOON SESSION—2 p. m.—(K) Unfinished business and new business. (L) Appointment of Standing Committees. (M) Election of President of League and place of the Executive Board. (N) Designation of place of next Annual Convention. (O) Adjournment.
EVENING SESSION—8.00 p. m.—Banquet or Smoker and programme of entertainment.

WIND VELOCITIES AT VARIOUS HEIGHTS.

From photographs and measurements of the waterspout seen off Cottage City, Mass., in August, 1896, Prof. Bigelow has recently calculated the wind velocities, etc., as follows, in miles per hour:

Height above Sea Level. Feet.	Diameter of Tube. Feet.	Velocity of Rotation. Miles.	Vertical Upward Velocity. Miles.
4,193	[illegible]	14.1	0.04
3,901	506	94.4	2.50
2,999	250	189.0	9.90
1,802	178	268.0	19.80
1,201	158	300.0	24.70
479	144	333.0	29.70
0	134	354.0	34.60

Dimensions and velocities like these characterize the largest tornado tubes and, together with the fall of internal pressure by the amount of three or four inches, readily explain destructive efforts such as those observed at Louisville and St. Louis recently.

The Council of the Royal Victorian Institute of Architects have adopted a scheme for a course in architecture, and cognate subjects to suit the requirements of articled pupils. The course will take three years at three nights per week, and the subjects will include architectural drawing, lectures, including sanitation, gas, water supply, quantities, and strength of materials, practical, plane, and solid geometry, and applied mechanics.

THE PROTECTION OF BUILDINGS AGAINST LIGHTNING

A paper of much practical value on this subject was recently presented by Prof. Reynolds, of the Ontario Agricultural College, Guelph, before the Mutual Underwriters' Association of Ontario. The author showed that trees, especially those with pointed tops such as poplars, elms and pines, being good conductors, act as protectors of nearby buildings. To the presence of trees in the streets he attributes the great exemption from damage by lightning of building in towns and cities as compared with country districts. In the country, owing to the cutting down of the trees, the damage by lightning is greater than 50 or even 30 years ago. Trees should however, not be too close to the buildings to be protected—not nearer than from 10 to 20 feet—as otherwise there is danger of a side flash from a tree striking the building and causing damage.

"There is perhaps, no tree which is a more efficient protector against lightning than the spruce used for ornamental hedges; that is just the thing for the purpose. This forms a natural protector against lightning. It is always in repair, and lasts practically for all time, and besides being a means of protection, its natural beauty adds to the permanent value of the property on which it is grown."

As regards artificial means of protection Prof. Reynolds recommended lightning rods, provided they were made of proper material, in proper form and rightly put up. If these conditions were not observed they became a source of danger instead of a protection. Copper conductors should be used weighing eight ounces to the foot, in flat form and attached to the building by proper insulators. In the opinion of the author the more points extending upwards from the conductor, the better. These points should be five or six feet high, and not more than 40 feet apart. It is essential that they be bright and sharp, as a bright point seems to have more attraction for lightning than a dull one. Aluminum is recommended as a material for points, because that material will not rust; it is always bright, and is a better conductor than iron.

"One of the most important points of all in providing for this sort of protection is in having a proper ground connection. It is an easy matter for a careless or dishonest agent to put the ground wire just a little below the surface; it is then out of sight, and he thinks out of mind as well. Wire buried just below the surface, in dry ground so far from being a means of protection, is a cause of danger, because the lightning, attracted by the points on the roof, is carried down the conductor, and if it is not then dissipated in damp ground, it is apt to fly off into the building. Protection can be ensured by seeing that the ground wire is connected with earth which is always moist. The depth necessary will depend upon the character of the soil and the location of the building. It may not be necessary to go over three feet, or it may be necessary to go ten feet; what is imperative is that the ground wire shall be connected with soil that is never dry. To this end it is best to put the ground wire in during dry weather. It is necessary to have more than a single wire in the ground. It is required to take such measures as will provide for the distribution of the current at the bottom. This can be provided for by flattening out an old copper boiler in sheet form and soldering that to ground wire; or take a number of stands of barb wire and connect these with the ground wire below the surface.

In the opinion of Prof. Reynolds the rodding of a building should be the subject of inspection at the time that the work is done, and provision should be made for periodical inspection after the rodding. Where this is done, there should be given something in the way of preferential rates to those who take this means of protection.

Sixty- five per cent. of the buildings struck in Ontario last year were barns. Of the buildings struck and burned, 80 per cent. were barns, one reason for this no doubt being that barns are nearly all frame, while many house are of brick or stone.

FIREPROOF CONSTRUCTION AND THE FIRE LOSS.

An appeal has been issued by Mr. Edward Atkinson the well known insurance expert, of Boston, for funds with which to establish an experiment station in the Massachusetts Institute of Technology. Mr. Atkinson has been prompted to take this step by having witnessed while in Europe last year, the benefit resulting from the experiments carried out in London under the direction of the British Fire Prevention Committee, whose work has frequently been referred to in these pages. As President of the Boston Mutual Fire Insurance Co. Mr. Atkinson has given the subject of methods of building construction in relation to fire prevention in textile factories much consideration, and has succeeded in effecting a large reduction in fire losses in such factories. He is now desirous of securing similar results from all classes of buildings.

Regarding the enormous fire loss in the United States, he says: The ash heap of the United States in the year 1901 exceeded one hundred and fifty million dollars ($150,000,000). If to this is added the excess of expense in conducting Insurance Companies, and the expence in water works and fire departments, all mainly due to the existence of avoidable danger in our great cities, we may compute the fire tax of this country in an average year at not less than two hundred and fifty million dollars ($250,000,000), probably more. That sum is more than the normal expense of conducting the United States Government in all its branches, omitting interest and pensions. It is equal to twenty (20) per cent. of the capital which can be added in a good year to the capital of the nation. It is considerably more than the annual appropriation for common schools; more than double the sum annually expended for the support of all our universities, colleges and technical schools, and yet there is no school where the elementary principles of prevention of loss by fire forms any part of the instruction.

In addition to the direct losses sustained by property owners and the insurance companies, enormous loss is inflicted upon the working class who are least able to bear it.

Methods of fire prevention as applied to buildings are deserving of much greater consideration than has thus far been given them on this continent.

An influential deputation, representing the Institute of Architects of New South Wales, recently waited upon the Under Secretary of Works, to impress upon the Government the desirability that designs for public buildings of a national character should, in future, be thrown open to competition.

CONCERNING STAINED GLASS.

In a lecture on this subject, before the Sheffield Society of Architects and Surveyers, Mr. A. Jeffery said that the first stained glass executed in England was in the time of King John. Previous to this all glass came from Italy, which even at this date boasted of eminent artists. The old masters taught us many lessons, and much could be learnt from them. We should try and embrace all the good qualities of the old men, ignore their shortcomings, and try to improve on what had been done before us. After the sixteenth century stained glass died out, and did not again revive until the nineteenth century. Mr. Jeffery went on to explain that a window should be part of a building, and should not be treated as a picture or wall decoration. If a man attempted a picture he spoiled his material as glass and made a very bad picture. As to the different methods of manufacture English glass was superior to foreign, both in material and workmanship. The most important point in a window was permanency, and only the most permanent of colours should be used, at whatever cost. Speaking of domestic glass, he did not think modern style was a passing fancy, but that it had come to stay, but like all other transitions in art at the outset it seemed to have been let loose, and we appeared to be seeking after something we could not quite grasp. The style, however, would ultimately settle down and find its own level. He was eagerly looking forward to the time when there would not be so much commercialism in connection with artistic crafts, and he hoped architects in the near future would come more into contact with the craftsmen, and by their joint ideas succeed in raising the standard of work.

DECORATION.

Lecturing before the Institute of British Decorators, in the Manchester School of Art, on "Decoration: its Methods and Materials," Mr. G. C. Haite remarked that the connection between architecture and decoration was of the greatest importance, and decorators should carefully study their relationship. Unfortunately in many cases of domestic decoration, with which one had to deal, there was no architecture worthy of the name; and to that extent, the decorator had nothing to work upon. There were people who ridiculed the idea of law in decoration. Applied art, however, depended on law. The essential principles, underlying everything else, were fitness and beauty. Decoration was subject to many limitations, and often these limitations conferred positive advantages. Take, for instance, the Moorish prohibition of the imitation of nature. As a result of that, we had the use of many forms showing very beautiful results. The limitations imposed by lines in lead light work were an absolute necessity, yet once recognised, what possibilities arose in their use. In stencilled ornament the fact of having to use ties imposed certain limitations. When properly employed, ties became a very effective part of the ornament. Coming to essentially modern forms of decoration, there appeared to be two schools of thought in existence, one of which would prohibit many examples of manufactured goods, believing that the true sphere of the decorator was in the production of ornament in the flat, and the other recognising that the goods made ready to hand were a product of the time, meeting real needs, and their use, therefore, quite legitimate. The first idea implies that every executant should be a designer, and he was in favor of this, if the men could only be found. We must differentiate, however, between a designer and a house-painter, for design required a master hand. He would urge upon all decorators the desirability of having private designs prepared for them by competent designers.

CHURCH OF ST. JEAN, MONTMARTRE.

The new church of St. Jean, at Montmartre, which is being built to replace the old Church of St. Pierre, adjoining the immense basilica of the Sacre Cœur, has again got into difficulties with the administration, and the Prefet de Police has given orders to the architect to stop the work of construction at once, and to proceed to demolish the building, which is now nearly completed. This church has already attracted considerable attention in architectural and building circles, first on account of the novel style of architecture which M. de Baudot, the well-known Diocesan architect, has given to his design, and again by reason of the nature of its construction, entirely in armoured brick and cement, called the Cottancin system. The Prefet de Police requires the immediate demolition of the church under a penalty of £4 per day of delay, simply because a proper demand for permision to construct was not made by either the architect or the vicar of the parish. The latter, considering that he had the right to build in spite of the Prefet, continued the work. It appears, however, that the Prefet is exceeding his rights, and that the vicar will win the day, for, according to the law relating to building rights, no demand for permission to construct a church on one's own property is necessary. The case is exciting great interest in Paris, for nearly £16,000 of building work has already been done on the church.

THE USE OF PORTLAND CEMENT.

Mr. H. H. Humphreys' in an exhaustive paper presented before the London Architectural Association traced the history of Portland cement and dealt with the question of testing. "The use of concrete in connection with expanded metal or with iron or steel rods has, I believe," said the author, "a great future before it, as the additional strength obtained by the introduction of the metal is vastly in excess of what mere theory would lead us to expect. In Germany and France and the United States this class of work is frequently met with, but up to the present time no very large amount has been carried out in this somewhat conservative country. It is bound to come, however, and considering the condition of what is generally called the 'skilled' labor market, it will be well if some substance (which it is possible to make by unskilled labor) can be subsituted for brickwork, as we may then hear that brick-layers are once more pleased to lay more than 400 or 500 bricks per diem. There may be a drawback, however, in using this armoured concrete, for unless the iron or steel, rods, joists, &c., are thoroughly protected, they will rust with great rapidity, and not only will their own strength rapidly disappear, but in addition to this the expansion of the metal in process of oxidation will cause disruptive forces to be set up in the heart of the work."

Prof. S. H. Capper, delivered an interesting lecture on Westminster Abbey before the members of the Province of Quebec Association of Architects on April 15th.

CORRECTION.

The Pite Competition design for park gate published in the April number of the CANADIAN ARCHITECT AND BUILDER was incorrectly credited to Messrs. Thos. McLaren and Andrew Sharp, A.R.I. B.A., Mr. McLaren's name alone should have been given as being the author of the design.

ARCHITECTURAL EXHIBITION.

The second annual Exhibition of the Toronto Architectural Eighteen Club will be held in the Ontario Society of Artists' galleries from the 19th to 31st inst. It will principally consist of photographs with quite a sprinkling of drawings ; the latter, however, will be a secondary feature of the Exhibition.

An illustrated catalogue will be issued at the opening of the Exhibition and will contain fifty full page illustrations of the most noted exhibits, and will endeavor to, if possible, outdo last year's issue in every respect.

LEGAL.

It is learned by the American Architect that a curious and important case has just been decided by the New York Court of Appeals. Some twelve years ago a block of three apartment houses was built on three contiguous twenty-five foot lots in New York by the owner of the three lots, who made the walls between his houses party walls. Not long ago, one Schaefer contracted to buy one of the lots with the house standing on it. After he had agreed to buy, he learned that the party wall, for a distance of twenty-seven feet, was entirely on the adjoining lot. He sued the person from whom he had agreed to buy for damages on the ground that he had not a complete house on the lot in question, since the support of a portion of the beams was on neighboring property. This view was confirmed by the Supreme Court, but the Court of Appeals held a different opinion, saying that the original owner of the three lots, by resting the beams of one of the houses on what was supposed to be a party wall, but which was really on the adjoining lot, created thereby a servitude on the latter lot, so that Schaefer was thereby entitled to rest his beams on the wall in question as long as it should stand ; and, as his house was so much wider in consequence, he was benefitted rather than injured, by the mistake.

One of the general conditions usually annexed to the articles of agreement between employer and contractor is to the effect that all additions, omissions, or variations made in carrying out the works for which a price may not have been previously agreed upon are to be measured and valued and certified for by the architect, and added to or deducted from the amount of the contract, as the case may be. The failure to insert such a clause says the London Builders' Reporter, resulted in a case being brought to the Chichester County Court on the 12th inst. Mr. H. A. Smith, builder, of Selsey, sued Mrs. S. Dent for the sum of £38 15s. 6d. for work done. The plaintiff contracted to erect a bungalow at Selsey for the sum of £740. While the works were in progress several alterations were made which resulted in the above claim, in addition to £20 already paid for as extras. Among other things, it was stated that plaintiff had to put on fresh grates; that he had to remove a cesspool which had been dug beneath one of the principal bedroom windows; to effect alterations in a gable to the roof and to repair the thatch, which was blown about by gales of wind, and to do certain extra work to chimney flues. Plaintiff's explanation as to the extraordinary situation of the cesspool was that he had first spoken to the architect on the matter. He charged £14 6s. for removing it to another part of the grounds. The defendant alleged that the contract had been unsatisfactorily carried out, and that the £20 already paid would cover all extra expenses. Mr. F. Swinburne, the architect, denied responsibility for the cesspool being constructed under the bedroom window. Evidence was also brought forward as to the unsatisfactory manner in which the contract had been carried out, considering the big price paid. The judge said there was no necessity for an action if it had been stated that the architect was to be sole judge. He disallowed entirely the charge made for removing the cesspool, and strongly commented on the position which plaintiff originally chose for the construction of the cesspool without the authority of the architect. The plaintiff was awarded £7 15s. 6d. in addition to the sum already paid.

NOTES.

Miss Kathleen Beverly Robinson, teacher of modelling in the Toronto Technical School, has won the first prize of $50 in connection with the competition for designs for crest for the King Edward Hotel.

Mr. C. H. Blackhall recently delivered an address before the Detroit Architectural Club on "The Architect That Might Be." He emphasized the five essential qualities of the successful architect.—Artistic perception, the personality and character of an educated gentleman, common sense, the sense of construction and business ability.

" Perhaps one way to forget style " says Mr. J. J. Burnett, A.R.S.A., President of the Glasgow Institute of Architects, " is to sink ourselves in human needs, for that, after all is the basis of all architectural expression. Refinement of mind and thought are to be used quite unconsciously in the service of our fellowmen, and when that is so there is no room to think of style at all; the first duty would seem to be to make buildings meet the necessities."

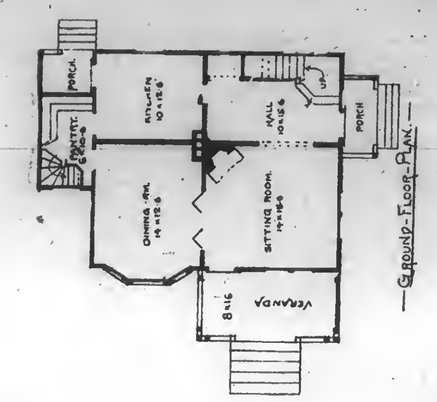
At the annual meeting of the Central Ontario School of Art and Design, held recently, the following gentlemen were elected as officers and directors for the ensuing year : President, Bernard McEvoy; vice-president and treasurer, W. Revell; secretary, George C. Downes; auditor, James Smith, R.C.A. ; directors, R. Y. Ellis, Robert McCausland, Eden Smith, Alderman S. G. Curry; J. D. Kelly, F. H. Brigden and George A. Howell.

By appointing Mr. Marshall, Director of Archæology in India, Lord Curzon has given the best practical expression of his wish and intention to do all in his power for the conservation of ancient monuments in India. The directions with which Mr. Marshall begins his work are very explicit, and it may be taken for granted that they will serve all purposes, including that referred to in the recent memorial from the British Indian Association, which is chiefly solicitous about the buildings appertaining to the Hindu religion in Bengal.

In reply to a correspondent the London Architectural Record gives the following as the requirements for successfully photographing architectural subjects:—We may briefly say, that the main requirements of an architectural photograph are that its vertical lines shall be vertical, its horizontal lines horizontal, its arches and windows shown complete and not cut in halves or quarters, its focus equal over the whole picture, its foreground, middle-distance and sky harmoniously arranged, and its composition truthfully rendered.

The management of the Louisiana Purchase Exhibition to be held in St. Louis, offer prizes of $2,500 for a design for a symbol or emblem to be used for the seal, stationery and advertising matter of every kind relating to the Exhibition. No rules are laid down as to lettering, sentiment, size or style of the design. The only stipulation is that it shall be symbolical of the great historical event which the Louisiana Purchase Exposition is to commemorate—the acquisition by the United States in 1803 for $15,000,000 from France, of 1,042,000 square miles of territory.

The horizontal mouldings serving as a sort of cap or cornice to the piers or arches, and on which the archivolts or curved mouldings and faciæ surrounding the arches themselves rest, are known as an impost. Like these latter, the impost is made plainer or richer, according to the order employed or to the general character of the design. And when the archivolts of the arches are omitted, either the impost is omitted likewise or a plain band substituted for it. This is generally done, says the Builders' Reporter, in basements beneath an order, they being usually rusticated, and the joints of the rustics sufficing for decoration and giving the requisite architectural expression. Imposts are contrary to the genius of the Pointed style, but, except in the case above alluded to, essential in Roman and Greco-Roman architecture. We have, however, a few instances in which imposts have been omitted, and the archivolt of the arch continued vertically down the edges of the piers. This was a favourite practice with Soane, both in his designs and many of his executed buildings, and it was also adopted by Burton in the arches of the Ionic screen and opposite gateway, Hyde Park Corner, Piccadilly ; but the effect is by no means happy, especially in external architecture, though it may be tolerated in buildings on a small scale, or which make no pretensions to correctness of style.



Cottage for Wm Wadds Esq.,

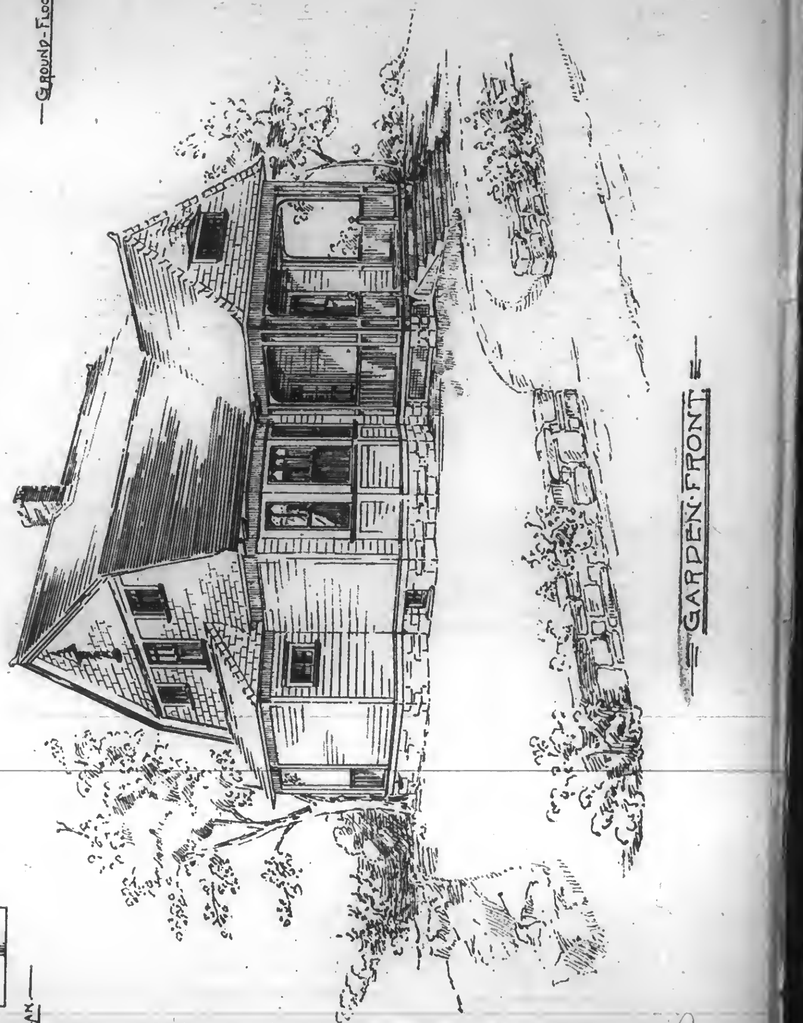
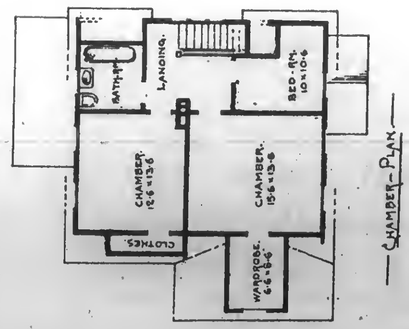
John J. Honeyman, ARCHITECT.
Rossland, B.C.





LOADS AND WORKING STRESSES FOR BUILDING WORK.

The committee appointed in 1899 by the Austrian Society of Engineers and Architects to report on "Specifications for the loading of structures, and the working stresses of materials of construction" has just (January, 1902) published the results of a two years labor. The following figures compiled from the report by Mr. F. C. Kunz, assistant to vice-president, Engineering Department, American Bridge Company, are of great interest for comparisons, says the Engineering Record, as they practically cover the same ground as our building laws. Items of local interest only, like data for special timber and for special stones, have been omitted. All figures are given in round numbers.

The figures have been carefully revised and such changes made as were necessry to adapt them to Canadian materials. The tables may be safely followed being based on 2200 lbs. to the ton. The table of working stresses is a little mixed, particularly that portion relating to timber, as the kinds of timber are not shown. However this matters but little as the calculations seem to have been made with some of the weaker woods.

Weight of Masonry.	Lbs. per cu. ft.
Common brick masonry, lime mortar	100-105
Common brick masonry, cement mortar	105-110
Hard brick masonry, Portland cement mortar	100-110
Best pressed brick masonry, Portland cement mortar	120-130
Hollow brick, lime mortar	80-90
Porous brick, lime mortar	70-80
Rubble masonry, light	140
Rubble masonry, medium	150
Rubble masonry, heavy	175
Ashlar masonry, sandstone	130-155
Ashlar masonry, limestone	125-160
Ashlar masonry, granite	200
Portland cement concrete, brick	110
Portland cement concrete, lime or sandstone	135
Portland cement concrete, granite	170

Weight of Building Material.	Lbs. per cu. ft.
Masonry debris	90
Sand	90
Slag	45
Coal ashes	45
Dry lime mortar	95
Dry cement mortar	105
Asphaltum	125-130
Gypsum	60-80
Cinder concrete	60-80
Glass	160
Dry earth	85
Wet earth	100
Gravel	125
Clay	95-110
Turf	10-25

Floor Live Loads.	Lbs. per sq. ft.
Mansard rooms	30
Residences	50
School rooms	60
Stairs, corridors, theatres, ballrooms, gymnasiums, armories, assembly rooms	80
Offices, light storage, above first floor	90
Offices, light storage, first floor	115
Ice storage (ice 3 ft. hight)	155

Wind and Snow. Loads.	Lbs. per sq. ft.
Hor. wind pressure on vert. plane	40
Snow pressure on horizontal plane	15

Only horizonal wind is to be assumed. If wind and snow loads are used combined, only two-thirds of the latter is to be considered.

Ultimate Bending Stress of Portland Cement Concrete Six Months Old.

Cement	Sand ; gravel.	Lbs. per sq. in.
1	3	600-710
1	3½	470-570
1	4	340-430

Permissable Working Stresses of Iron, Timber and Glass. In pounds per sq. in.

	Tension	Comp.	Bending	Shear.
Wrought iron and ingot iron	14,200	14,200	14,200	11,400
Cast iron	2,850	8,530	3,560	2,850
Glass cast	1,000		850	
Glass blown	1,000		650	

All rivet holes have to be drilled. Maximum pressure on bearing surface of rivets, 23,000 lbs. per sq. inch. For iron and wooden bridges special instructions exist.

The working stresses of timber.

Tension, from	1,140 to 1,420
Compression, from	850 to 1,000
Bending from	1,140 to 1,420
Shear, parallel to grain	140 to 210
Shear, perpendicular to grain	280 to 420

Buckling and eccentric loading have to be considered. (No formula given).

Permissable Working Stresses of Dimension Stones and Piers. In tons per sq. ft.

	I	IIa	IIb	IIc
Hard granite	100	60	50	25
Medium granite, hard limestone	70	40	30	..
Hard sandstone, medium limestone	50	30	25	..
Medium sandstone, soft limestone	35	20	15	..
Soft sandstone	15	10		

I refers to single dimension stones, with a factor of safety of about 15 ; IIa to piers whose height does not exceed 6 to 8 times their least dimension ; IIb to piers whose height does not exceed 8 to 12 times their least dimension ; and IIc to piers whose height does not exceed 12 times their least dimension. For all stones except granite, which are kept continually wet, these figures do not apply.

Permissable Working Stresses for Other Masonry. In tons per sq. ft.

	a	b	c
Common brick, lime mortar	5	7·5	10
Common brick, Roman cem. mortar	7·5	5	..
Common brick, Port. cem. mortar	10	7·5	5
Rubble, lime mortar	4	..	..
Rubble, Roman cem. mortar	5	..	..
Rubble, Port. cem. mortar	8	..	..
Coursed rubble, Port. cem. mortar	10	..	..
Hard brick, Port. cem. mortar	12	8	6
Best pressed brick, Port. cem. mortar	20	15	10
Concrete for foundations : Roman cement 1, sand and gravel 5	5	..	..
Concrete for walls : Portland cement 1, sand and gravel 3	18	..	..
" " 1, sand and gravel 5	12	..	..
" " 1, sand and gravel 8	8	..	..
" " 1, sand and gravel 10	6	..	..

In these groups a refers to walls not under 18 inches thick and piers whose height does not exceed 6 times their least dimension; b to walls under 18 inches thick and piers whose height does not exceed 6 to 8 times their least dimension ; and c to piers of at least 12 inches smallest dimension, whose height does not exceed 8 to 12 times their least dimension.

Permissable Working Stress in Masonry Arches up to 30-Foot Spans. In tons per sq. ft.

	Compr.	Tension
Common brick, lime mortar	6¾	0
Common brick, Roman cem. mortar	70	0
Common brick, Port. cem. mortar	10	1
Hard brick, Port. cem. mortar	12	1
Best pressed brick, Port. cem. mortar	20	0
Concrete, Port. cem. 1, sand and gravel 3	18	3
Concrete, Port. cem. 1, sand and gravel 5	12	2
Concrete with iron (Melan, Monier, etc., systems), Port. cem. 1, sand and gravel 3	21	8
Dimension stones, (exept soft sandstone) in Portland cement mortar	25	1

The figures are based on a mortar of 1:3.

Permissable working stress for stone stairs can be taken as one-fifth of the ultimate stress for bending.

Permissable Pressure on Foundations. In tons per sq. ft.

Soft clay and wet sand	1.0
Ordinary clay and dry sand mixed with clay	2.0
Loam, hard clay and sand without clay	4.0
Firm coarse sand and gravel	6.0

Piles in loose, wet soil should not be stressed more than 350 lbs. per sq. in. of their cross-section. They should be placed not more than 3 ft. apart.

Mr. W. E. Doran, architect, was recently appointed to the Montreal Board of Harbor Commissioners.

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited.
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.
Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

SPECIFICATIONS FOR PAINTING IRON AND STEEL.—The following are extracts from regulations drawn up in the painting specifications by one of the principal continental railway companies for the painting of iron and steel work:—"All ironwork must be thoroughly cleansed by scouring with wire brushes and benzolene or by steeping in dilute hydrochloric acid, the acid to be afterwards neutralized with lime water and finally rinsed with hot water and dried. The ironwork is then given a coat of pure linseed oil which has been heated to 100 degs. Fahr., which must be allowed to thoroughly dry. The work is then given two coats of genuine red and one coat of white lead mixed in boiled linseed oil, to which has been added from two or three per cent. of litharge or lead acetate. Each coat of paint must be allowed to dry before applying the next and in favourable weather. When three or more coats are applied, each coat of paint should differ somewhat in colour, in order to determine the number of coats applied.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

Photographic Exhibition.

An exhibition of architectural photographs is a dull thing. The photograph is honourably matter of fact, no doubt, and tel's no deliberate falsehoods; but it cannot be said, in the fullest sense, to tell the truth. In the first place, of course, the very important element of colour is left out; not only in the building, but in the surroundings which do so much to set it off. In the second place the point of view is limited and the effect from an imperfect point of view is less satisfactory seen through a limited lense than through an adjustable and reasoning eye. The complaint of painters, that people see things not as they appear to the eye but as they know them to be, is not on the whole a bad thing. We may be unperceiving sometimes of the pictorial effects of nature; but for practical purposes when a man is finding his way across the country, for instance, it is of less importance that he should enjoy the effect of a purple patch of shadow in the middle distance than that he should know it means a bridge. In the same way the eye is able to translate perspective back to the facts it represents, and see in an extremely sloping line the effect of a level cornice. But more than this the eye has a way, if it is an intelligent eye, of selecting the most interesting points and ignoring those which are unimportant. A man of taste before a well composed building sees it as it was meant to be seen, with his attention fixed upon the essentials; and if he were to draw it would bring out these essentials. A photographic lense on the other hand is just as particular about the non-essentials; when confronted with a family group, as amateur photographers well know, it seems to devote its best efforts to the wall paper and picture wires. This cannot be called an artistic representation. For artistic representation we want a statement that is like a good story—the points all in, the twaddle all out; and the photograph is too much like an old woman's tale—laying equal emphasis on major and minor points—to satisfy this requirement. As a study in design, a drawing which brings out a little more favourably than can be done in nature the points of the design, is perhaps more profitable than a photograph which tends to overwhelm the points with minor details more than would be the case in nature. An exhibition of drawings is certainly more interesting.

Correspondence Schools.

It is somewhat surprising to hear that the Architectural League had anything to say in favor of the Correspondence Schools. They have the merit of marking down a course of reading for the solitary student and giving him a stimulus to carry it out—in great part the stimulus of feeling that his course is costing a good deal of money and he must not throw it away. On the other hand

Photographic Exhibition.

An exhibition of architectural photographs is a dull thing. The photograph is honourably matter of fact, no doubt, and tells no deliberate falsehoods; but it cannot be said, in the fullest sense, to tell the truth. In the first place, of course, the very important element of colour is left out; not only in the building, but in the surroundings which do so much to set it off. In the second place the point of view is limited and the effect from an imperfect point of view is less satisfactory seen through a limited lense than through an adjustable and reasoning eye. The complaint of painters, that people see things not as they appear to the eye but as they know them to be, is not on the whole a bad thing. We may be unperceiving sometimes of the pictorial effects of nature; but for practical purposes when a man is finding his way across the country, for instance, it is of less importance that he should enjoy the effect of a purple patch of shadow in the middle distance than that he should know it means a bridge. In the same way the eye is able to translate perspective back to the facts it represents, and see in an extremely sloping line the effect of a level cornice. But more than this the eye has a way, if it is an intelligent eye, of selecting the most interesting points and ignoring those which are unimportant. A man of taste before a well composed building sees it as it was meant to be seen, with his attention fixed upon the essentials; and if he were to draw it would bring out these essentials. A photographic lense on the other hand is just as particular about the non-essentials; when confronted with a family group, as amateur photographers well know, it seems to devote its best efforts to the wall paper and picture wires. This cannot be called an artistic representation. For artistic representation we want a statement that is like a good story—the points all in, the twaddle all out; and the photograph is too much like an old woman's tale—laying equal emphasis on major and minor points—to satisfy this requirement. As a study in design, a drawing which brings out a little more favourably than can be done in nature the points of the design, is perhaps more profitable than a photograph which tends to overwhelm the points with minor details more than would be the case in nature. An exhibition of drawings is certainly more interesting.

Correspondence Schools.

It is somewhat surprising to hear that the Architectural League had anything to say in favor of the Correspondence Schools. They have the merit of marking down a course of reading for the solitary student and giving him a stimulus to carry it out—in great part the stimulus of feeling that his course is costing a good deal of money and he must not throw it away. On the other hand

they have the demerit of calling the course of reading a qualification, which it is not. They advertise in such a way that draughtsmen and builders' foremen think that this is the short road to become an architect. The result is an increase of the unskilled who do not know that they are unskilled, and a neglect of less attractive but more substantial means of training. Time will no doubt disprove the undue pretensions of these Schools, but at the cost of much loss and disappointment to students ; and if any professional body speaks in praise of the system there should at the same time be strict recognition of its limitations. There can of course be no question of a Correspondence School as a substitute for the Scientific Schools of McGill and Toronto University, but students should be warned against thinking it a sufficient substitute for the course of study and examinations of the Associations of Architects.

Building Permits.

Just how numerous and glaring are the defects of the so-called Toronto Building By-law, is known only to those who like architects and builders have intimate relations with the Building Department. Let us take as example the unnecessary and vexatious regulations governing the issue of a building permit. The Building Inspector's Department will refuse to grant an architect a permit until a receipt is produced from the waterworks department showing that payment has been made for the water which will be required by the contractor in erecting the building. This means that the architect must either take his plans to the water department and wait while the officials figure up from them the probable quantity of water required by the builder, or leave them behind and go or send for them the next day. There is no good reason why architects should be put to all this trouble and delay. If the plans when submitted by the architect are found to conform to the by-law as interpreted by the Building Inspector, the permit should issue forthwith. Arrangements for the supply of water should lie with the water department and the contractor. Advance payment for the water could easily be insured by the city refusing to turn on the water except on production by the contractor of a certificate of payment from the water department.

Architects and Landscape Architects.

Mr. Pentecost's paper, read before the Architectural League, points clearly to a conclusion, which he forbore to press, that, when the site of a building is sufficiently important to require the intervention of a landscape architect, he is the paramount designer. Repton, as quoted in the paper, is less modest. "Repton's position," Mr. Pentecost says "is, that while the landscape architect should have no official voice in the actual designing of the house, the style and general arrangement, location and disposition of the house and grounds should be officially determined by the necessities of the landscape architect's general plan ; for, as Repton says further, 'to my profession belongs chiefly the external part of architecture, or a knowledge of the effect of buildings on the surrounding landscape.'" All this is quite true. The site prescribes the character of the building ; the building aims to be as it were a part of the site ; and if the architect is obliged to call in a landscape architect to enable him to understand the possibilities of the site, it goes without saying that he must base his design upon the understanding thus received. This is all Mr. Pentecost spoke for—co-operation. But there is a dark hint lying in his statement that "the true solution of the problem rests with the progress and recognition of landscape architecture as a profession." He goes on to show that there has been hindrances to the development of of this profession—to its development that is to say, from landscape gardening, as it used to be called, to landscape architecture. When fully developed and recognized are we to expect that the landscape architect will rise from being employed by the architect to employing the architect? Will the co-operation, that Mr. Pentecost rests upon, change from an architect inviting the co-operation of a landscape gardener to the landscape architect inviting the co-operation of a house planner? It is the logical sequence. The major quantity fixes the condition for the minor. As the house (that is the architect) fixes the conditions for the supplementary arts of painting and sculpture, so the site (that is the landscape architect) should fix the conditions for the house. But logical consistency is an imperfect guide to life. The house is after all the principal thing. It is more impossible for the landscape architect to grasp the requirements of that problem than it is for the architect to seize upon the points of a site—and take advice from a landscape specialist.

The Education of Architects.

THERE is something most praiseworthy in the continual discussion by architects of means for the better education of students, but there is surely something that can be done by architects to educate themselves and each other. The absence of this element from the discussions of architects gives a strange air of unreality to their talk about education. It is of course useless to the cobwebs, and a surprising amount of good feeling talk of set studies, or problems, or prizes for busy architects, but Mr. Bispham Page spoke a bottom truth when he pointed out that an architect learns the best things he knows after he has begun practising ; and the question is whether architects would not materially hasten each others' development by a systematic exchange of ideas. Meeting to study problems in the abstract is too laborious and it is school boy work any way ; but the study of current problems, which constitutes this post graduate course, which Mr. Page speaks of, which architects are taking all their lives, could be made more profitable and much quicker in operation by meeting other architects systematically for mutual criticism and discussion. The old fashioned jealousy of architects for one another has almost disappeared, under the influence of greater culture ; it indeed, in the matter of design, it has not altogether disappeared. There is no reason why it should exist. There is so much individuality in art that however much a man may give of his ideas he will never find that they are taken up by others in the same way he has taken them up. If every one pours freely into the the fund of common experience there will be a gain all round, without increase of conflict, for, though every man takes from it the same material, it will be found worked up into different products. He who contributes most to discussions of this kind will gain the most; for, by the effort of explaining his ideas, he will clear them up as they never were before. Clear thinking is the fruit of expression, and one reason why it is so difficult to get contributors to professional paper reading and discussion is, that there is so little clear thinking and so much disinclination to the effort of thinking clearly. There ought therefore all the more be a prosperous career for a series of meetings to which members could bring, not their discoveries, but their doubts and difficulties. It is twice as easy to solve a problem in conversation as alone ; and if there is no solution, if the designer is up a blind alley, as so often happens in design, a light from outside is the quickest way to show him where he is. Architects could improve one another incalculably by regular meetings for mutual criticism.

The Durability of the Steel Frame.

THE rumour that the pulling down of a twelve year old steel frame building in Chicago has shown its lower columns to be half eaten through with rust contradicts the evidence of the gridiron foundations of the old post office which after a longer term of years, if we recollect rightly, were found to be in good order inside their cement casing. But if this rumour is true, (and doubt is cast upon the preservation of iron in cement), it will be a serious addition to the uncertainty which is felt as to the life of a steel frame building. This discussion has been revived in the American papers and reports of experts are so contradictory that the question may be said to rest in doubt. In the meantime steel frame buildings are being rushed up more than ever and we may be sure that carefulness does not increase with familiarity. Representations have been made of the danger of efflorescent brickwork in contact with the steel frame. If the corrosive salt is as freely efflorescent on the inside as it is on the outside, the wall can hardly be called a protective casing. Is any brickwork in fact sufficient protection to a metal which must be kept from exposure, not to the weather merely, but to the carbonic acid convyeed in ordinary air. It is possible to blow a candle out through a brick wall, by placing the candle at the small end of a funnel held tightly against one side of a brick wall, while the mouth is applied to the small end of a funnel held tightly against the other side exactly opposite. There must therefore be a continual change of air between the inside and the outside of an ordinary brick wall. How much carbonic acid accompanies the change depends upon the amount detained by the mortar. The affinity of lime and cement for carbonic acid must be taxed by sudden changes of temperature or in a high wind when the change of air in the walls is rapid, and there must come a time of satiation when the mortar can no longer be relied upon to stop the passage of the gas. Brick and terra cotta surrounding a steel frame is supposed to be grouted so as to be impervious to air, but it is doubtful if it can be made so at the best, if we may trust the evidence of tests for the permeability of walls, and there is sure to be much laxity in practice.

On the whole there is not enough certainty about the protection of the steel frame buildings ; but they are being built in greater and greater numbers. It is said that twenty-four millions worth of office buildings have been begun in New York this season and steel frame construction is in progress for uptown buildings also. The centre of commerce has moved up a good deal ; and above that apartment houses grow taller and taller, in the effort to accomplish the end of making the same limited area hold an increasing population. About the time New York is solid with steel frame buildings the catastrophe to the earlier buildings of the kind—if there is going to be a catastrophe—will be due. In view of this state of affairs insurance companies are interested and the question of durability is going to be thoroughly tested by an Experiment Station, established by the efforts of Mr. Edward Atkinson, under the direction of a member of the staff of the Massachusetts Institute of Technology.

THE SECOND ANNUAL EXHIBITION OF THE TORONTO ARCHITECTURAL EIGHTEEN CLUB.

The Toronto Architectural Eighteen Club is to be heartily congratulated on the very successful nature of its Second Annual Exhibition which was held during the last week of May in the Galleries of the Ontario Society of Artists.

The exhibits consisted mainly of photographs, a few pen and ink drawings and some pastels and water colors. The subjects were of remarkable range and variety, for the Architectural League of America was well represented and some fine European photographs were loaned ; Montreal, Quebec and Vancouver all assisted to lend increased interest to the collection.

Some of the photos were chiefly remarkable as photographs, the subjects being scarcely entitled to such excellent reproduction; on the other hand, photography with its inherent defects of perspective, failed to do justice to many of the subjects.

As the exhibition was by no means confined to members of the Eighteen Club, it is to be regretted that so many of Toronto's architects were not represented. Such exhibitions can have none but a beneficial effect, by bringing architects together, brushing away and good fellowship is generated ; it it is good for one to mix with one's fellow men surely it must be still better to associate with fellow workers, to exchange ideas and broaden our views. Every architect to whom the advancement of art is more than a mere phrase should endeavor to be represented at this exhibition in the future.

The real live interest shown by our United States friends in this and similar exhibitions is instructive ; they send hundreds of beautifully framed and mounted photographs from many different points widely scattered over a continent to help out a numerically small Architectural Club in Canada ; their genuine interest in the welfare of architecture and their belief in the good derivable from such hearty co-operation is quite clearly demonstrated, and it is to be hoped that every Architectural Society in the Dominion will emulate this friendly example.

If I may venture to offer a suggestion, I think the interest in the exhibition could be greatly enhanced if small scale sketch plans more frequently accompanied the photos, more particularly of interiors. The soul of a design lies in the plan and if the true value of the design is to be appreciated its plan must be shown or at least indicated.

I cannot make mention of every interesting work as the catalogue, which by the by was rather late in making its bow, contained so much that was admirable. I can only make reference to some of those numbers which appealed most strongly to me: Messrs. Bailey & Truscott, Philadelphia, sent a fine collection of photos of executed work, a quaint "Colonial" Exterior, No 11, and a quiet gabled house with half timbered upper stories, No. 22, being particularly attractive.

It is difficult to judge sculpture from rather small photographs in which both scale and technique are almost lost, but the "Stitch" (in clay ?) of Commodore Bainbridge & Stewart, No. 124, seemed to give promise of much greater interest than the other work shown by H. K. Bush Brown (Newburg, N. Y.), though the group, "Indian Buffalo Hunt," No. 122, shows life and spirit.

Messrs. Cope & Stewartson, Philadelphia, contributed a round dozen of fine photos, every one representing work worthy of their reputation: No. 155, "Entrance to House at Edgehill," is simply exquisite, and No. 157, "Dormitories, University of Pennsylvania, from the Terrace," is a fine piece of transplanted English collegiate building.

Of Nicola D'Asanzo's decorative designs, No. 171, "Ball Room Decoration for W. W. Gibbs, Esq.," is a singularly fine composition. The remainder probably depend largely upon the scheme of co'or, which is of course lost in the photos. "Egypt Awakening," No. 190, F.F. Elwell, is in my opinion far ahead of all the other exhibits of sculpture.

No. 212, "Dining Room, Codmore, Hyland," (H. G. M. Gordon) and Nos. 55 and 56, "Dining Room" by A. H. Brokie, Philadelphia, are specially quiet and reserved.

Nos. 236 to 242 is a series of enlargements admirable in light and shade and peculiarly interesting as illustrative of the American Garden.

"Pantry Fittings," by Messrs. Kennedy & Kelsey, of Philadelphia, is a wonderful little bit of skillful contrivance, and the photo of a Mantel, probably in the same house as the Crystal Palace of a Pantry, is as refined as it is effective.

A good collection of photos of Port Sunlight, lent by Sproatt & Rolph, Toronto, indicate the happy result of several architects all working on similar lines and in sympathetic accord.

No. 295, "Bachelor Apartments," F.M.Mann, with an oak hall, kindly rendered by both architect and photographer.

Nos. 298 to 299, Mewman, Westman & Harris, Philadelphia, seemed to me to be the softest and most beautiful photos in the collection, the play of light and shade about the picturesque half timbered house in the trees being quite charming. For the furniture I can find little good to say. Nos. 317 to 320, C. Rholfs, Buffalo, appears to me to confound subtle simplicity and direct carpentry with sheer affectation and then smothers the unfortunate result with surface ornament, which is not bad in itself but so shockingly ill applied. Some designs of furniture seem to abhor a plain surface even of very beautiful material.

H. W. Weller, Montreal, sends Nos. 405 and 406, "Some Typical English Beauty Spots."

Judging from the bronze work, Nos. 411 to 417, by John Williams, New York, it would seem that funds are not doled out to the architect in the United States in the 10 cents at a time measure that is too commonly the case in Canada; but it is this very point which emphasizes the great difference between United States and Canadian Architecture. The Toronto architect has to exercise a degree of self restraint that his confrere across the border seems to wot not of. Rarely indeed can the Canadian architect let himself go because he has so commonly to solve problems involving the greatest possible return for the minimum outlay, and in Toronto the result is for the most part extremely gratifying, as may be seen by referring to the numerous exhibits of work by the President, which illustrates most aptly how a simple and dignified effect may be gained entirely by means of good lines, careful grouping and clever fenestration; all the detail being thought out and applied with a sparing and subtle hand.

This self command is evident in much of the work of other exhibitors, and the English influence is also very marked in Messrs. Burke & Horwood's lovely little Bible Training School. And the garden front to "Castle Frank" and the Stables by the same gentlemen are delightful.

No. 368 to 376, "House in Queen's Park," by Messrs. Sproatt & Rolph, further illustrates the growing grip that the English influence is taking on Toronto; Messrs. Lever Bros. premises by the same authors emphasizes this fact very successfully.

Nos. 378 to 381 are exceptionally good pen and ink perspectives of Symons & Rae's new University Buildings at Kingston,.

No. 144 is perhaps the most pleasing example given of Chadwick & Beckett's work: E. J. Lennox is represented by some very fine enlargements of photos of his well-known work in the city.

No. 444, "An Artist's House," H. Payette, Montreal, is a pretty French villa such as one sees at Strasburg, for instance.

The impression received from this exhibition is that the influence of the French school is but little felt in Toronto, and that the so-called "Colonial" of the United States which has been so absolutely boiled to rags by ardent caricaturists in Canada as well as in the United States, has little hold upon Toronto. The influence of the modern English school on the other hand has rooted deeply in a congenial soil, and in so many able hands will doubtless greatly thrive in the near future. Toronto has a great architectural future and if the members of the profession will but work together the Queen City will probably give the note to the character of Canadian Architecture.

ROBERT M. FRIPP.

The modelling and carving of an immense frieze on the Stanford University memorial arch, in California, marks the completion of a colossal undertaking in sculpture. The arch is over 100 ft. high and is built of Sau Jose limestone; running around it at a height of 80 ft. is the frieze, illustrating American civilization. The total length of the frieze on the four sides of the structure is 232 ft.; its height is 12 ft. It contains 150 heroic figures in high relief.

THE ARCHITECTURAL LEAGUE OF AMERICA.

For the first time the Architectural League of America met in annual convention on Canadian soil. The fourth convention opened in the Gallery of the Ontario Society of Artists, King St. West, Toronto, at 2 p. m. on May 29th., Mr. J. C. Llewellyn, the President, presiding. Among those in attendance were the following: J. C. Lewellyn, Chicago Architectural Club; E. J. Russell, St. Louis Architectural Club; Charles Pfeil, St. Louis Architectural Club; A. C. Barrett, Eden Smith, William Rae, Charles E. Langley, J. C. B. Horwood, C. H. Acton Bond, Henry Sproatt, J. Francis Brown, A. C. Barrett, J. P. Hynes, Toronto; Dwight Herald Perkins, Robert Craik McLean, (editor Inland Architect), Chicago; Newton A. Wells, Champaign, Ill.; Francis S. Swales, Detroit Architectural Club; Cheri A. Mandelbaun, Detroit; Frederick G. Todd, Montreal; Frederick William Strabenger, Ira O. Hoffman, Albert E. Skeel, Cleveland, Ohio; Herman Krégelius, Cleveland Architectural Club; William Laurie Harris, Frederick S. Lamb, John Harder, Geo. Pentecost, Jr., H. K. Bush Brown, New York; Emil Lorch, Chicago Architectaral Club, Cambridge, Mass.; A.C. Williams, Chicago Architectural Club; Henry D. Bates, Architectural Review, Arthur D. Rogers, Boston.

MR. ALBERT KELSEY, Past President, Philadelphia.

MR. EMIL LORCH, Corresponding Secretary, Chicago.

The delegates from the United States were welcomed to Toronto by the President of the Toronto Architectural Eighteen Club, Mr. Eden Smith. The President in his reply referred to the small attendance as due to the Convention being held at a time of the year when architects were unusually busy.

Mr. E. J. Russell, of the St. Louis Architectural Club, was elected speaker of the Convention, Mr. Albert E. Skeele, of Cleveland, Ohio, Secretary, Mr. Julius F. Harder, New York and Mr. C. A. Mandelbaum, of Chicago, auditors.

The report of the Executive Board presented by Mr. Llewellyn stated that the past year had been an uneventful one, the work of the League having been largely carried forward by the Committees. The board recommended that adequate provision be made for the publication of the proceedings. Several applications to aid in securing legislation of interest to architects had been referred back to the Clubs for individual action. The report of the Committee on Circuit Exhibitions showed that difficulties had been encountered in carrying on these exhibitions according to schedule, and that some new arrangement would probably have to be made. The report of the Committee on Current Club Work stated that there had been an increase in membership in nearly all the Clubs during the year, and that much attention had been given to the subject of municipal improvement, many of the Clubs working in harmony with the municipal authorities. This was particularly the case in Cleveland and St. Louis. The Cincinnati Club had set a good example to the other Clubs by making a collection of photographs and drawings of interesting old buildings. Reports were read showing in detail the work on which the various local Clubs have been engaged during the year. These reports showed that the expense of the exhibitions held under the auspices of the Clubs forming the League, had ranged from $1,300 to $8,000, and that the interest manifested by the public had been very disappointing. On this point, Mr. Pfeil, of St. Louis, stated that the Club which he represented were finding it more difficult every year to raise the money for their exhibition. The admission fees received amounted to only $30 or $40, the balance of $2,000 having to be raised by advertising. It was found that by joining the Artists' Guild a larger attendance and greater interest was secured.

MR. HERBERT B. BRIGGS, Cleveland.

For the Architectural Eighteen Club of Toronto, Mr. J. P. Hynes, the Secretary, reported as follows:

"We are not able to report any increase in our membership, but I think we have a reason that makes that excusable. We have had in Toronto for fourteen years an Association of Architects, but its aims and purposes are quite different from ours. So we have kept the membership of our Club small, thinking that in that way we could best do our work. We have carried out two exhibitions, both of which have proved to be financially successful. One direction in which the Club has worked has been in the matter of education. The building in which this Convention is meeting is really an Art School. Night classes were going on here without any architectural class, but architectural classes are now included and the members of the Toronto Architectural Eighteen Club give the instruction. There were eighteen students registered last year. Mr. Bond is chairman of the committee in charge of that work, and some of the problems worked by the students appear in drawings on these walls.

In the matter of municipal improvement we have not done much in Toronto so far but talk. We have had communications with the Ontario Government in regard to the faulty location of a large building now in course of construction for the School of Practical Science. We have also had communication with the municipal authorities in regard to having a proper plan for the Exhibition Park, but have been unsuccessful. Following that we joined with the Guild of Civic Art to protest against granting to a Baseball Club a piece of property which we thought would be detrimental to the city to grant for such a purpose. We had a conference with the Manufacturers' Association which has shown some interest in artistic improvement, and which on the occasion of the Duke of York's visit to Toronto erected an arch at their own expense. We have also had several conferences with the city authorities with the view of having a plan adopted for municipal development, and hope yet to succeed. Our principal work this year has been the making of plans for this Convention. We have held our present Exhibition in the effort to make your visit interesting. It is a very modest one, being composed chiefly of photographs, but we hope you will appreciate our efforts in the matter."

Professor Newton A. Wells in reporting for the Toledo Club protested against the admission to the Circuit Exhibition of work which was below the proper standard. Mr. Bush-Brown intimated that undesirable exhibits could be weeded out by the individual Clubs. Mr. Llewelyn suggested that it might be a good thing to make the Circuit Exhibition of photographs only, leaving the local Club to supplement these with drawings. Mr. Swales, of Detroit, thought if the object of the exhibitions was to educate the public to appreciate better design, photographs or water color would be found to be better than line drawings. The following resolution wss passed on motion by Mr. Harder: "That proper photographs of architectural, decorative painting, and sculpturesqe subjects should not be generally excluded from exhibitions, but should be admitted and such photographic reproductions should in future form the nucleus of the Circuit Exhibition".

Mr. Frederick S. Lambe, of New York, urged that an effort be made to bring into the League allied organizations, having an interest in promoting the objects that the League has in view. Professor Wells moved that a committee be appointed to bring in a recommendation on the subject, and the following were appointed a committee for that purpose: Messrs Harris, Llewelyn and Bush-Brown.

GROUP PHOTO OF PERSONS IN ATTENDANCE AT THE CONVENTOIN IN TORONTO OF THE ARCHITECTURAL LEAGUE OF AMERICA.

At the evening session Mr. Bush-Brown presented the report of the committee on Municipal Improvement. This Committee reported in favor of the recommendation that had been made to broaden the scope of the League by endeavoring to secure the alliance and co-operation of other societies.

The report was adopted.

Mr. Llewelyn introduced a resolution that Mr. Bush-Brown be requested to write a lecture, illustrated by lantern slides, to be used as part of the Circuit Exhibition, and that accompanying this lecture should be a travelling library of civic improvement literature. The resolution was seconded by Mr. Lambe and carried.

Mr. Geo. F. Pentecost, Jr., of New York, presented an interesting paper on "Landscape Architecture," referring particularly to the relations between the architect and the landscape architect. On motion by Mr. Hynes, a vote of thanks was tendered to Mr. Pentecost. This was followed by a paper by Mr. Charles Mulford Robinson, of Rochester, N.Y., read by Mr. W.L. Harris, of New York, on "Civic Art as Evolution, Not Revolution", for which a vote of thanks was tendered to the author. Mr. Julius F. Harder moved an amendment to the Constitution changing the date of holding the Annual Convention from Thursday to Monday. Mr. Hynes moved that section 25 of article 8 of the Constitution be amended to read: "The Annual Convention shall be held at 10 o'clock a.m. at such place and on such date as shall be designated by the previous Convention, and that paragraph "n" of section 28 be amended to read " Designation of time and place of next Annual Convention". The motion carried. After adjournment for luncheon, a group photograph of the gentlemen attending the Convention was taken by request of the publishers of the CANADIAN ARCHITECT AND BUILDER. The afternoon was spent on the lake and concluded with a dinner at the Royal Canadian Yacht Club.

At the morning session on the 30th the Committee re Exhibit of Model City at St. Louis Exposition submitted the following resolution:

"Whereas the improvement of towns and cities is a subject of widely recognized importance to the people of the United States, and whereas civic improvements of a permanent character must soon transform any community, "reflecting man in his full twentieth century developments," exhibiting not alone his material but his social advancement in a most conspicuous manner, and whereas science and art in modern city building have formed a subject of department exhibits at three international exhibitions abroad, therefore be it resolved that the Architectural League of America in Annual Convention assembled petition the commissioners of the Louisiana Purchase Exposition to make provision for an exhibit which shall have these characteristics.". The resolution was adopted and a copy ordered to be sent to the commissioners. A number of short papers on various phases of the educational question were presented from Louis H. Sullivan, Chicago, William L. Harris, New York, Herbert H. Briggs, Cleveland, Percy Ash, Washington, Professor Newton A. Wells, of the University of Illinois, John W. Case, of Detroit. These papers all had a bearing on the subject of education in schools and universities and were supplemented by letters from gentlemen connected with various universities. The reading of the papers and letters was followed by a lengthy discussion of the following points:

(1) Is a National American Art University a desirable or necessary Institution?

2. Should the National Government have connection with or jurisdiction over a National Art University, or should the organization and control be similar to that existing in American Universities?

The preponderance of opinion expressed was in favor of a National Art University founded on broad lines and subsidized by the Government. Professor Wells was of opinion that such a University should include the workshop. He did not belleve it possible to teach the theoretical side of art or to make a designer without requiring the student to work in the material.

At the morning session on the 31st a paper was presented from Geo. D. Page, of Philadelphia, on "Club and Inter-club Self Education". Mr. Llewelyn in discussing this paper expressed the opinion that the old method of educating the draughtsman by starting him in an architect's office has gone by. The new men coming into the offices are all products of the scientific schools, hence the necessity of the League placing itself in as close touch as possible with these schools. The Club should be made as attractive as possible and an effort put forth to get the graduates of the scientific schools as members. A paper on the same subject was read by Mr. Emil Lorch, of Cambridge, Mass. In the discussion following, several of the speakers gave testimony in favor of the value of the work done in behalf of architectural students by the Correspondence Schools. Mr. Dwight L. Perkins, of Chicago, read a paper on "Architecture and Citizenship".

Some further discussion took place with regard to the Circuit Exhibitions, Mr. Pfeil making the suggestion that a prize be offered for the best example of architecture exhibited in the photographs comprising the Exhibition. The various suggestions made on this subject were refered to the Committee on the Exhibition Circuit.

At the afternoon session the following Committee were appointed: "Publicity and Promotion"—Frederick S. Lambe, New York, Chairman, James P. Llewelyn, Chicago, and the new President. "Auxiliary Committee on Publication and Promotion"—D.C. Boyd, Philadelphia, Chairman, Mr. Blackhall, Boston, Mr. Perkins, Chicago, Mr. Hewett, Brooklyn, Mr. Skeel, Cleveland. " Code of Ethics ahd Competition "—Julius F. Harder, New York, Chairman, Messrs. Striebenger, Cleveland, Shean, New York. "Current Club Work"—E. J. Russell, St. Louis, Chairman, Messrs. Hayes, Philadelphia, Hynes, Toronto. " Education" Emil Lorch, Cambridge, Mass., Chairman, Messrs. Ash, Washington, Case, Detroit. "Publicity and Records", Emil Lorch, Cambridge Mass., Chairman, Messrs. Skeel and Kregelins.

On motion by Mr. Hynes, those scholars who win the travelling scholarships of the Clubs which send scholars to Europe were appointed a Committee on foreign exhibit of the League. This Committee will consist of Mr. J. H. Phillips, of the Chicago Club, and Mr. Morris Leisenring, of the Philadelphia Club.

The Convention next proceeded to the election of officers. Messrs Frederick S. Lambe, of New York, and Ernest J. Russell, of St. Louis, were nominated for the office of President. Mr. Russell withdrew in favor of Mr. Lambe, who was unanimously elected. It was decided to hold the next Convention at St. Louis on Monday and Tuesday, the 12th and 13th of October, 1902. The following gentleman were appointed as a Committee on Exhibition Circuits: Mr. Harris, New York, Chairman, Mr. Kleinpell, Chicago—the third member to be appointed by the President.

Votes of thanks were tendered to Mr. Skeel, the Secretary of the Convention, and to the Toronto Architectural Eighteen Club. Afterwards the Convention adjourned.

THE BANQUET.

Following the conclusion of the business sessions a banquet was tendered the visitors by the Toronto Architectural Eighteen Club at McConkey's Restaurant.

Responding to the toast, "Our Guests," Professor Wells said: When I started from home to come over here, I will tell you what I thought, and I know the rest thought the same; "we are going over

to that Eighteen Club ; that is a small Club composed of energetic, good-hearted fellows, and we are going over here to give them a lift, and to pat them on the back." But, confound it, when we got over here it was just the other way—we are the little end of the horn. I have not been at any convention where we have been more handsomely treated or more profoundly impressed with the energy and seriousness of the work we have seen. We had prided ourselves on being Yankees, possessing the energy of the world; but we are going back home with the intention of trying to keep up to the band-waggon. (Applause).

On behalf of the Ontario Association of Architects, Mr. Edmund Burke responded in humorous vein as follows :

Mr. President, I did not expect to be called upon to say anything here this evening—I regret that the President of the Ontario Association is out of town, and neither our Vice-President nor our Second Vice-President are here.

I think the discussions of last night, particularly, must have affected me.

I did not remain as long at the closing ceremonies as Professor Wells. I understand I missed a good deal—I had but a cracker, some cheese and a glass of ginger ale, and left at a respectable hour. If I had remained later I might have had a more lurid experience, but even as it was, I had, that night, or rather in the early morning hours a curious dream—I do not know if it was caused by "The Information of Knowledge" (see programme of convention) or the cheese or the ginger ale, but it was somewhat like this, (and I do not know but that a Joseph or a Daniel will be needed for the interpretation thereof). A building took shape; it was orthodox in design—column, entablature, and cornice of correct proportions. On one side was an archway. The handsome wrot. iron gates swung suddenly open, and out dashed a well equipped hook and ladder waggon; the buckets dangling beneath were labelled O.A.A. and the crew had helmets with the same initials. But the curious part of the outfit of the crew was their coats. They were made of Whatman's double elephant paper with plans and elevations neatly drawn and titled. In place of buttons they were secured with thumb tacks which occasionally became unfastened. The nearest fireman to the man whose coat became unfastened would drive the pin into its place by a whack from a pike pole, causing a momentary wince on the part of the party of the first part, indicating that the pin had penetrated more than sufficient distance.

Another building took shape. It had a dado chin-high; upon this were set columns in groups; they were four diameters high, they each had fourteen flutes and a plain space which I found, on spacing off with a divider left room for four more. The volutes of the wide spreading caps were turned upside down; the frieze was six feet high and the cornice six inches with a projection of five feet, and half of the six inches was occupied by dentils, each six inches wide, at one quarter inch spaces. This building had, likewise, an archway, with real bronze gates. Instead of bars or panels each leaf was composed of the Roman numerals XVIII with horizontal top and bottom bars held together with a vertical rod thus ⊞.

In some positions, like the signs you sometimes see, you could scarcely make out the XVIII, but, open, shut or half shut the bars remained visible. Out of this archway dashed a little spick-and-span chemical engine with a thirteen inch gong on the dashboard. The buckets were labelled XVIII, and the helmets of the crew likewise. They were also dressed curiously. Their coats were black prints on a white ground, and colored with aniline ink. The coats did not come unbuttoned—they had no buttons—they were made out of whole cloth, and fitted without a wrinkle.

I forgot to mention that the hook and ladder wagon was drawn by horses. The chemical engine was a gasoline locomobile, and one could not help knowing when it was around—within a block or two.

Well, just as the hook and ladder wagon was turning a corner the off horse slipped and fell bringing the wagon to a sudden halt. The chemical was close behind and before one could say "Jack Robinson", had dashed into the wagon. The chemical tank exploded with a loud report, and the fumes smothered both crews.

At this point my front gate clicked and I heard the milk-man clattering up with his bottles to the side door.

While I mused on the interpretation of this dream I dozed off again, and had another:

I saw in my vision a magnificent dog-cart. The wheels were about seven feet in diameter, and I counted thirteen spokes in each. The high seat was about twenty-four inches higher than the low seat—(remember this was a real dream). It was drawn by a tandem team of fourteen horses—hackneys I think, and the little shaft horse was a most restive colt—always nipping the haunches of the nag in front of him, in order to make him move ahead a little faster. I observed that there were four spare sets of harness stowed away under the seat—I presume for that many additional horses by and by.

The cart had red and white stripes painted around the box—thirteen, I think I counted, and one oblong panel had a lot of stars in it.

The driver was a fine young fellow, I should say about 6.333 ft. tall, and he looked well on the high seat. He remarked to me that he had a fine team—most of them thirty six hands high. I said he was talking nonsense. He said he had measured them and showed me the scale. I called his attention to the fact that he had used the ⅙ inch instead of the ¼. He then said they were eighteen hands high, and proceeded to demonstrate the fact. I then showed him that he had included the dead ends of the scale and that they were just fourteen hands high, fair measurement. He then remarked that they were "goers, anyhow".

On the lower seat I noticed a smallish man, with sandy whiskers of Lord Dundreary type. He wore a stove-pipe hat about nine inches high, innocent of curve or entasis, and with a flat rim. Its color was faded and ancient—about the shade of the India ink seen on the drawings of the students in the exhibition. It was a pretty old hat, though still useful.

The old gentleman wore a fob, and a large seal graven with the letters O. A. A.

The young chap had a large white tag pinned to his coat, on which was printed A. L. A.

The old gentleman smilingly listened to my conversation with the young man, occasionally nodding his head, whether in approval of what I said or what the other chap said I could not discover.

The A. L. A. chap then tickled the shaft horse with his whip. The shaft horse thereupon nipped the rear elevation of his neighbor, and as they were vanishing in the distance the old gentleman shouted, "we are going to drive through the suburb of Hamilton, then on to Suspension Bridge and then on to the Great American Art University at Buffalo". I though he emphasized the word "Suspension"—possible it had no connection with the University.

Just then my front gate clicked again, and the iceman tumbled a cake of ice on the side steps. I slept no more after that.

Gentlemen it has been an inspiration to me, and I feel sure to the other members of our Association who have heard the discussions at your Convention on art matters. I regret that we as an Association have not been able to show you much attention, but you have been so well entertained and your time has been so fully occupied that there has been no opportunity. We hope, some day, to meet you again and to have this opportunity.

FOUNDATIONS ON QUICKSAND.*

Meriden lies in a valley between high hills. In the valley, which is claimed by some to be the original bed of the Connecticut River, is a soil which consists of sandy loam, a little gravel and plenty of quicksand. Most of the buildings in this valley rest on the skin which is found at various depths below the surface, and here the Meriden Gas Light Company bought a 300 by 500-feet meadow lot adjoining its works on which to erect a new holder. Careful borings were made over a section 120 ft. wide by 250 ft. long to determine the thickness of the gravel, if any, and its distance below the surface. To the west of this section, and 25 feet distant, runs a shallow brook, 20 to 30 feet wide—shallow except in freshet time. About seventy-five tests were taken, and the result laid out and plotted into curves, so that the most desirable place for the site might be located. The top material was a sandy loam, evidently a silt deposited from the overflow of the brook when in past years it was not so confined ; the next a good gravel, but very thin ; below that a quicksand of unknown depth. At a few points the gravel was found as near as 2 feet from the surface and 2 feet thick, while at the others it was 8.5 deep and only 0.4 thick, shading off to nothing. The average depth, however, taken from the boring stations, was 5.5 ft. deep and 1.2 ft. thick. A boring of 50 feet taken in the centre of the site showed 42 feet of quicksand and still more below.

On such materials it was decided to construct the foundation and erect a steel tank-holder, to be 115 feet in diameter and 103 feet high; holding 700,000 feet of gas in three lifts. The weight of the ho'der to be 475 tons and the weight of the water to be 8,625 tons or a total of 9,100 tons.
